13. ABSTRACT (Maximum 200 words)

A systems engineering approach to the development of a warship optimized for the deterrence of regional conflicts in littoral waters is presented, followed by a description of the preliminary design of the ship shown by analysis to be most effective. The requirement for the project reported was to develop a ship which would be effective in deterring regional wars among third world nations; in hampering the military effectiveness of the aggressor should deterrence fail and in protecting or evacuating limited numbers of civilians. The study reports on an analysis of likely threat weapons, on the means used to choose defensive combat system capabilities to defeat such weapons and on the selection of capabilities necessary for successful operation in littoral waters. Major emphasis is placed on measures intended to significantly improve the ship's survivability relative to existing combatants. The design description includes data and numerous drawings.

A Regional Deterrence Ship, RDS 2010

This report presents a systems engineering and design capstone project undertaken by students in the Total Ship Systems Engineering program at the Naval Postgraduate School. The project was performed under the direction of Prof. C. N. Calvano. (The officer students who comprised the design team were: LCDR Dwight Alexander, LCDR Dean Cottle, LT Kent Ketell and LT Jeff Riedel, all USN.)

ABSTRACT

A tentative operational requirement was given to the development team, calling for analysis and design of a ship which would be highly effective, through presence-projection, at operating in littoral waters to deter regional conflicts between third world nations and at hampering the military operations of the aggressor nation in the event the deterrent effort failed. The ship was also required to have significant capability to support the evacuation of friendly personnel; to be fully capable to be operationally integrated into a battle group; to support limited amphibious operations (conducted from other ships) and to have robust self-defense (but not area defense) capabilities. Because the ship would be operating in a high-tension area, it is likely to be fired upon from a peacetime footing and, therefore, was required to have significant vulnerability reduction features.

The report documents the identification of threat weapon characteristics and the analysis of four possible threat attack scenarios. For each scenario, the team required that the RDS 2010 be capable of achieving a kill probability in excess of .99 against all assumed threat weapon combinations. The report describes the analyses conducted and the combat systems suite selected to be incorporated in the ship.

Minimization of the likelihood and numbers of crew casualties was a high priority design guideline and the report discusses the various design alternatives considered to reduce the ship's vulnerability to threat weapons. A double hull was incorporated, providing significant reserve buoyancy, a measure of additional standoff distance against warhead detonations and providing the necessary volume for incorporation of yet-to-be-defined measures for defeating warhead effects. Considerable care was given to the arrangements of combat capabilities in *enclaves* to reduce the likelihood of loss of multiple capabilities from a single hit.

A complete description of the ship resulting after the first iteration of preliminary design is provided and considerable detail in the description of the ship is provided in appendices.

I. INTRODUCTION

This paper is the final report for the Total Ship Systems Engineering (TSSE) student design project for the TSSE class of 1993. This report represents the compilation of all work performed over a two quarter period from October 1992 through March 1993. The various assignments and design products created have been integrated into this one design report to provide a detailed and comprehensive record of the work completed.

The design of the Regional Deterrence Ship (RDS) 2010 (formerly known as the Force Projection Ship (FPS) 2010) included all facets of a real design, though some detail had to be omitted in the interest of time and resource constraints. Overall, the project included the following major design phases:

- (1) Requirements Setting
- (2) Threat Environment and Analysis
- (3) Combat System Definition
- (4) Hull, Mechanical, and Electrical Feasibility Tradeoff Studies
- (5) Preliminary Design and Cost Analysis
- (6) Design Evaluation

The chapters of this report will include salient results of these design phases and other relevant material.

Figure 1-1 illustrates the timeline of the major evolutions which occurred during the two quarter design effort. Appendix A contains the design history which chronicles the major design decisions associated with the various design phases.

Figure 1-1. Design Timeline.

II. REQUIREMENTS SETTING PHASE

The requirements setting phase of the ship design process begins with the articulation of a need that is not being met by the current ship inventory. For this class, the professors acted as the "operators", representing the OPNAV structure. They articulated the geopolitical view of the world in the year 2010, with specific emphasis on the Naval roles and missions in this world view. Based on these roles and missions, they then postulated a Force Projection Ship (FPS) to meet a specific niche in the required U.S. defense posture. They defined in general terms the roles and capabilities of this envisioned ship, intending it to be the CNO top level guidance to kick off the design study.

The report provided by the professors is included in the pages which directly follow. The student design team was tasked to produce a requirements document for submittal to the CNO. This requirements document would then be given back to NAVSEA (the design team) to initiate feasibility studies for the FPS-2010.

A. CNO TENTATIVE REQUIREMENT STATEMENT

1. World View-2010 time frame

In terms of global reach, the world will be unipolar, with only the U.S. possessing meaningful global reach capabilities. The fundamental U.S. - FSU (Former Soviet Union) relationship will be one of cooperation--rather than competition--on most issues. This relationship, however, is becoming less important because the FSU is becoming fragmented to such an extent that, except for nuclear weapons capability, it possesses virtually no attributes normally associated with superpower status.

In regional terms, the 2010 world will be multipolar and the fundamental relationship among regional powers, on most issues of importance, will also tend to be more cooperative than competitive. The world will seem "kinder and gentler" in most respects, although potentially destabilizing developments will continue to bubble just below the surface in several of the world's traditionally troublesome regions. Any one, or a combination, of these could erupt and result in international crisis conflict in the near future.

a. The U.S. Navy will continue to require the ability to:

- (1) operate in a forward-deployed mode, far from U.S. shores, for lengthy periods of time;**
- (2) project power ashore via tactical air power and cruise missiles;**
- (3) conduct opposed amphibious assaults;**
- (4) protect U.S. interests and U.S. nationals worldwide.**

b. In this changed world, however, blue-water Naval engagements with a powerful adversary Navy will not be a threat. U.S. Navy operations are likely to have the following characteristics:

- (1) take place mostly in littoral waters off the shores of nations which are now frequently referred to as "third-world";**

(2) be of a peacekeeping or tension-reducing nature; Navy ships will find themselves introduced into volatile areas for the purpose of "cooling" down adversary nations within a region (transition from "peacetime" conditions to active engagement may occur without warning);

(3) be intended to remove U.S. nationals from trouble spots, or show U.S. resolve to protect its nationals as well as its other interests in the area;

(4) be part of a collective security organization (e.g. UN) sanction-enforcement effort and take the form of trade interdiction or embargo;

(5) consist of strike operations intended to "decapitate" an aggressor nation's war fighting capabilities, or opposed landings of limited size forces (up to Marine brigade size), or covert insertion of special forces;

(6) be challenged by nations with modern equipment (probably purchased from "first world" powers) in limited numbers; but operated in a skilled and determined way.

2. FPS Role in 2010

The study team sees the role of the envisioned FPS-2010 as follows:

- a. lengthy deployment, world wide;
- b. operations in all oceans (but not in polar regions);
- c. either independent or Battle Group operations;
- d. AAW (self defense but not area defense) against attacks launched by third world nations;
- e. ASW against nuclear and non-nuclear submarines in shallow water;
- f. ASUW against third world surface naval forces;
- g. presence projection;
- h. keeping ports and choke-points open to peaceful sea borne commerce;
- i. support of special operations;

- j. destruction of high-value, land-based Military targets;
- k. support of amphibious assaults;
- l. operations in mined areas;
- m. interdiction of contraband-carrying ships.

3. Political Considerations

It is clearly in the best interests of the United States to be able to intervene early in potential regional violence in order to avert it or, at least, affect the outcome. However, such actions will not be acceptable if they carry a high price tag--in dollars, in international political impact or in American lives. Therefore, a surface ship to fill these roles must be designed to minimize:

- a. the probability (and numbers) of crew member losses;
- b. the probability of loss of the ship;
- c. the share of the shrinking defense budget that the ships represent;
- d. the probability of causing damage to non-combatants or neutrals.

4. Other

It is anticipated that 8 to 10 of these ships would be built.

Summary:

The design team's requirements document is included next. This is the result of a few iterations of submittals and revisions between NAVSEA (student design team) and CNO (professors). One major change that occurred during this process was a change in the name of the ship from *Force Projection Ship* (FPS) to *Regional Deterrence Ship* (RDS).

B. REQUIREMENTS DOCUMENT FOR REGIONAL DETERRENCE SHIP (RDS) 2010

1. General Description of Operational Requirement.

The Chief of Naval Operations (CNO) and Joint Chiefs of Staff (JCS) guidance for the Navy in the decade beginning in 2010 describes a change in emphasis and requirements for Naval combatants designed to be deployed in that time frame. The world will be unipolar with only the United States possessing meaningful global reach capabilities. The intense Cold War adversarial relationship with the republics of the former Soviet Union will have changed to one of cooperation on most issues. The republics of the former Soviet Union will possess virtually no attributes normally associated with superpower status, with the exception of their remaining nuclear weapons arsenal and capability.

The regional view of the world will be multipolar with the fundamental relationships between regional powers being more cooperative than competitive on most germane issues. However, potentially destabilizing developments will continue to simmer amongst nations in some traditionally troubled regions. As nations emerge from under unifying but repressive regimes, traditional ethnic strife will come to the forefront. These regional friction points could involve U.S. citizens and erupt into international incidents resulting in a crisis that draws in the United States.

To operate effectively in the world environment of 2010, a balanced Navy force structure is required which includes a Regional Deterrence Ship (RDS). The RDS 2010 is needed to meet the challenge of a reduced blue water threat while enhancing the capabilities required for operating in the coastal waters of third-world nations. The RDS 2010 will effectively show an American presence in any part of the world as a peacekeeping and tension reducing tool and show American resolve to protect U.S. citizens in a volatile region. Additionally, the RDS 2010 will be capable of operating as

part of a collective security force with the ability to project power ashore while minimizing its own vulnerability and susceptibility.

2. Threat

The U.S. Navy faces a threat in 2010 primarily from modern and capable weapon systems possessed and skillfully operated by third-world nations in limited regional engagements. These weapon systems are purchased from first-world powers such as the U.S., its allies, China and member states and former allies of the former Soviet Union. The capability, skill, and determined manner in which these weapons may be deployed, though contained to a limited region, must be appreciated. The RDS 2010 must be capable of successfully defending itself while penetrating this weapons environment to complete its tasks. Specifically, these threats include:

- a. air and surface launched anti-ship missiles with all categories of sophisticated homing techniques;
- b. surface and submarine launched torpedoes in shallow water engagements;
- c. waters mined with all varieties of mines;
- d. small and medium caliber gunfire from coastal patrol craft;
- e. biological and chemical agents;
- f. attempted boarding by determined and professional forces.

Third-world nations have possessed and used many of the above listed weapons and techniques with increasing frequency over the past twenty-five years.

3. Shortcomings of Existing Systems.

To support the Navy's mission against the threats enumerated in Sections II.B.1 and II.B.2, the present inventory of U.S. Navy ships and ship acquisition schedule is too costly considering the drastically reduced defense budget. Present ships in the inventory are either over designed to meet conventional aspects of the above threat, and thus too expensive to send into such an unconventional environment, or lack the fundamental

capabilities to engage or survive encounters with the specific threat categories listed in Section II.B.2. Specifically, no ship in the current inventory will effectively:

- (a) conduct shallow water ASW;
- (b) support the variety of aircraft associated with joint/coalition style force structures;
- (c) transfer ("hand-off") AAW self-defense information between own-ship systems; or
- (d) remain in a high readiness condition for a prolonged period without crew performance degradation.

Additionally, since pre-attack threat recognition is nearly impossible and defensive reaction time is exceedingly short during hostile encounters in congested coastal waters, the probability of a hit is high. The present ship candidates available to meet the mission needs have inadequate self-defense and survivability features.

4. Range of Capabilities Desired.

The RDS 2010 shall provide the following capabilities:

- a. sustain a six month forward deployment with a two week replenishment interval;
- b. completely integrated shipboard combat system;
- c. AAW self defense against limited intensity/duration attacks;
- d. ASUW against third world surface naval forces;
- e. ASW in deep and shallow water while employed independently;
- f. support amphibious assaults;
- g. attack high value land based military targets (both coastal and interior);
- h. receive real time targeting information from diverse sources;
- i. interdict contraband carrying ships;
- j. operate in mine infested waters;

- k. rapidly configurable C³ system for interoperability with joint/coalition forces;
- l. operate at highest readiness condition for two weeks at a time;
- m. operate in chemical, biological, and radiological environments;
- n. operate in all oceans, less polar, in at least sea state five;
- o. transit all major commercial shipping canals and waterways;
- p. maximum speed of 25 knots for 85 hours;
- q. endurance: 4000 nautical miles at 16 knots, followed by 20 days on station at 8 knots with a 400 nautical mile withdrawal distance at 6 knots;
- r. projected lifetime of 40 years;
- s. low signatures to avoid being detected, targeted or hit (enhance deception effectiveness.);
- t. have special features to enhance the ability to fight hurt;
- u. shock qualification required;
- v. semiautomatic intelligent damage control system with remote sensors;
- w. support short duration, covert operations;
- x. incorporate an appropriate SSES;
- y. support flight operations of non-assigned joint forces helicopters;
- z. carry a surgeon and have operating room facilities.

5. General Affordability Limits.

The acquisition cost of RDS 2010 will not exceed 500 million dollars.

6. Platforms/Quantities.

Approximately 10 ships will be built.

7. Integrated Logistics Support (ILS).

Two key factors drive the required maintenance support for this class of ship: (1) forward based maintenance assets are not anticipated, and (2) lengthy,

independent operations remote from other naval assets are anticipated. Therefore, incorporated into the ship design will be the following ILS features:

- a. Built-In-Test-And-Evaluation (BITE) capability in all weapons, sensors, communications, and supporting vital equipment; Automated Test and Evaluation (ATE) capability to troubleshoot and fault isolate to replaceable components all removable and repairable circuit card assemblies; adequate manning and facilities to support micro-miniature component repair;
- b. phased maintenance concept with a 15 year overhaul cycle for major system upgrades;
- c. modular design of weapons, sensors and communications systems to facilitate system upgrades;
- d. arrangement of machinery and equipment, including shipping/unshipping paths, to ease the change-out of equipment components and minimize adjacent system interference ripout (this facilitates at sea replacement and repair and lowers regular maintenance availability costs);
- e. commonality of components for all ship systems, unless a significant loss of system performance would result;
- f. automated component monitoring system in the engineering spaces to aid in phased maintenance planning and to minimize engineering watchstanders;
- g. manning not to exceed 175.

8 Related Efforts.

TASM capability will continue to be available. To support the maintenance needs of this class, a forward deployable tender capability will be maintained.

Summary:

This requirements document kicks off the actual ship design process. These requirements are translated into desired operational capabilities which form the backbone of the ship design. The ability of the ship to perform these operational capabilities is a major judge of ship performance to design guidelines. The Required Operational Capabilities are included in the next section.

C. REQUIRED OPERATIONAL CAPABILITIES

Based upon the Range Of Capabilities Desired (Section II.B.4), the following primary and secondary Required Operational Capabilities (ROCs) and design requirements are delineated:

1. Primary ROCs

- a. *AAW self defense against limited intensity/duration attacks*
- b. *ASUW against third world surface naval forces*
- c. *ASW in deep and shallow water while employed independently*
- d. *rapidly configurable C³ system for interoperability with joint/coalition forces*
- e. *receive real time targeting information from diverse sources*
- f. *operate in chemical, biological, and radiological environments*
- g. *operate in all oceans, less polar, in at least sea state five*
- h. *attack high value land based military targets (both coastal and interior)*

2. Secondary ROCs

- a. *support amphibious assaults*
- b. *interdiction of contraband carrying ships*
- c. *support short-duration covert operations*
- d. *incorporate an appropriate SSES*

3. Primary Design Requirements

- a. *operate in mine infested waters*
- b. *sustain a six month forward deployment with a two week replenishment interval*
- c. *completely integrated shipboard combat system*
- d. *operate at highest readiness condition for two weeks at a time*
- e. *operate in chemical, biological, and radiological environments*

- f. operate in all oceans, less polar, in at least sea state five**
- g. transit all major commercial shipping canals and waterways**
- h. maximum speed of 25 knots for 85 hours**
- i. endurance: 4000 nautical miles at 16 knots, followed by 20 days on station at 8 knots with a 400 nautical mile withdrawal distance at 6 knots**
- j. have special features to enhance the ability to fight hurt**
- k. semiautomatic intelligent damage control system with remote sensors**
- l. carry a surgeon and have operating room facilities**

4. Secondary Design Requirements

- a. projected lifetime of 40 years**
- b. low signatures to enhance deception effectiveness**
- c. shock qualification required**
- d. support flight operations of non-assigned joint forces helicopters**

Table 2-1 shows the primary required operational capabilities applicable to this ship as taken from standard Navy ROC definitions.

TABLE 2-1. PRIMARY REQUIRED OPERATIONAL CAPABILITIES.

ANTI-AIR WARFARE (AAW). The destruction or neutralization of enemy air platforms and airborne weapons, whether launched from air, surface, subsurface, or land platforms.

- AAW 6 Detect, identify, and track air targets.
 - AAW 6.2 Recognize by sight friendly and enemy aircraft which may be encountered in expected operating areas.
 - AAW 6.3 Maintain accurate air plot.
 - AAW 6.4 Measure aircraft altitude with radar.
 - AAW 6.5 Detect, identify and track air targets with radar.
 - AAW 6.6 Acquire and track air targets with gunfire and missile control systems.
 - AAW 6.9 Conduct radar approaches for embarked aircraft.
 - AAW 6.* Detect and track air targets with an infrared sensor.
- AAW 9 Engage airborne threats using surface-to-air armament.
 - AAW 9.1 Engage high speed, med/long range airborne threats with med/long range missiles.
 - AAW 9.3 Engage low altitude threats with missiles and gunfire.
 - AAW 9.4 Engage low/medium/high altitude airborne threats with gunfire.
 - AAW 9.7 Engage airborne threats using portable missile systems.

ANTI-SURFACE SHIP WARFARE (ASUW). The destruction or neutralization of enemy surface combatants and merchant ships.

- ASU 1 Engage surface threats with anti-surface armaments.
 - ASU 1.1 Engage surface ships with long range cruise missiles.
 - ASU 1.2 Engage surface ships with medium range cruise missiles.
 - ASU 1.4 Engage surface ships with major caliber gunfire.
 - ASU 1.6 Engage surface ships with minor caliber gunfire.
 - ASU 1.9 Engage surface ships with small arms gunfire.
- ASU 4 Detect, identify, localize, and track surface ship targets.
 - ASU 4.1 Detect, localize and track surface contacts with radar.
 - ASU 4.2 Detect, identify, and track surface contacts visually.
 - ASU 4.5 Detect, identify, and track surface contacts with infrared equipment.
 - ASU 4.6 Detect, identify, and track surface contacts by ESM.
 - ASU 4.7 Identify surface contacts.
- ASU 6 Disengage, evade, and avoid surface attack.
 - ASU 6.1 Employ countermeasures.
 - ASU 6.2 Employ evasion techniques.
 - ASU 6.3 Employ EMCON procedures.

ANTI-SUBMARINE WARFARE (ASW). The destruction or neutralization of enemy submarines.

- ASW 5 Provide for air operations in support of airborne anti-submarine operations.
 - ASW 5.1 Launch rotary wing aircraft involved in anti-submarine operations.
 - ASW 5.2 Recover rotary wing aircraft involved in anti-submarine operations.
 - ASW 5.4 Provide required conventional ordnance to support anti-submarine operations.
 - ASW 5.6 Conduct operations during all EMCON conditions.
 - ASW 5.7 Load/unload ordnance compatible with required aircraft turnaround times.
- ASW 7 Engage submarines with anti-submarine armament.
 - ASW 7.2 Attack with ASROC.
 - ASW 7.4 Attack with mortar/depth charges.
- ASW 8 Disengage, evade, avoid and deceive submarines.
 - ASW 8.1 Employ torpedo countermeasures and evasion techniques.
 - ASW 8.2 Employ acoustic countermeasures against submarines.

MOBILITY (MOB). The ability of Naval forces to move and maintain themselves in all situations over, under, or upon the surface.

- MOB 1 Steam to design capability and in the most fuel efficient manner.
 - MOB 1.1 Steam at full power.
 - MOB 1.2 Steam with split plant operations.
 - MOB 1.7 Transit at high speed.
- MOB 3 Prevent and control damage.
 - MOB 3.1 Control fire, flooding, electrical, structural, propulsion, and hull/airframe casualties.
 - MOB 3.2 Counter and control CBR contaminants/agents.
 - MOB 3.3 Maintain security against unfriendly acts.
 - MOB 3.5 Provide damage control security/surveillance.
- MOB 7 Perform seamanship, airmanship, and navigation tasks.
 - MOB 7.1 Navigate under all conditions of geographic location, weather, and visibility.
 - MOB 7.2 Conduct precision anchoring.
 - MOB 7.3 Get underway, moor, anchor, and sortie with duty section in a safe manner.
 - MOB 7.4 Abandon/scuttle ship rapidly.
 - MOB 7.7 Provide life boat/raft capacity in accordance with unit's allowance.
 - MOB 7.15 Operate in chemically contaminated environment.

- MOB 10** Replenish at sea.
- MOB 10.1 Receive vertical replenishment.
 - MOB 10.2 Receive fuel while underway (alongside method).
 - MOB 10.3 Receive munitions and provisions while underway.
 - MOB 10.6 Receive fuel while underway (astern method).
- MOB 12** Maintain the health and well-being of the crew.
- MOB 12.1 Ensure all phases of food service operations are conducted consistent with approved sanitary procedures and standards.
 - MOB 12.2 Ensure the operation of the potable water system in a manner consistent with approved sanitary procedures and standards.
 - MOB 12.3 Maintain the environment to ensure the protection of personnel from overexposure to hazardous levels of radiation, temperature, noise, vibration, and toxic substances per current instructions.
 - MOB 12.5 Monitor to ensure that habitability is consistent with approved habitability procedures and standards.
 - MOB 12.6 Ensure operation and maintenance of all phases of shipboard environmental protection systems do not create a health hazard and are consistent with other naval directives pertaining to the prevention of pollution of the environment.

STRIKE WARFARE (STW). Support the destruction or neutralization of enemy targets ashore through the use of conventional weapons.

- STW 3** Support/conduct multiple cruise missile strikes either independently or in support of other strike forces.
- STW 3.2 Support/conduct conventionally armed cruise missile strikes.

COMMAND, CONTROL AND COMMUNICATIONS (CCC). Providing communications and related facilities for coordination and control of external organizations or forces and control of unit's own facilities.

- CCC 3** Provide own unit's command and control functions.
- CCC 3.1 Maintain a CIC capable of collecting, processing, displaying, evaluating, and disseminating tactical information.
 - CCC 3.3 Provide all necessary personnel services, programs, and facilities to safeguard classified material and information.
 - CCC 3.4 Carry out emergency destruction of classified matter and equipment rapidly and efficiently.
 - CCC 3.5 Employ Identification Friend or Foe/Selective Identification Feature (IFF/SIF) secure IFF mode 4.
 - CCC 3.6 Coordinate and control the operation of remotely piloted vehicles.
 - CCC 3.8 Establish voice communications with U.S. Marine Corps (USMC) evacuation and command nets and Naval Support Activity (NSA) net.
- CCC 4** Maintain Navy Tactical Data System (NTDS) or data link capability.
- CCC 4.3 Transmit/receive and support Link 11.
 - CCC 4.5 Receive and process data link information from Satellite Communication (SATCOM).
 - CCC 4.6 Receive and process data link information from High Frequency (HF) systems.
 - CCC 4.7 Receive Link 14 information.
 - CCC 4.10 Transmit/receive and correlate targeting information with Link 4A.
- CCC 6** Provide Communications for own unit.
- CCC 6.2 Provide visual communications.
 - CCC 6.3 Provide multi-channel cryptographically covered teletype send and receive circuits.
 - CCC 6.4 Provide uncovered Radio-Teletype/Continuous Wave communications.
 - CCC 6.5 Provide full duplex cryptographically covered IIF teletype circuits.
 - CCC 6.10 Provide voice/teletype/computer data cryptographically covered satellite communication circuits.
 - CCC 6.11 Establish and provide fixed combat communications and relay support for NSW operations.
 - CCC 6.12 Provide internal communications systems.
 - CCC 6.16 Provide tactical, secure, anti-jam Ultra-High Frequency (UHF) voice communications.
 - CCC 6.18 Provide tactical, secure, anti-jam HF voice communications.
 - CCC 6.19 Provide tactical, secure voice or data communications.
 - CCC 6.20 Provide internal Ship Signal Exploitation System (SSES) communications system.

III. INITIAL DESIGN DECISIONS

At this point in the design process, several elements must essentially come together simultaneously. First, based upon the capabilities that this ship must possess and the political factors addressed in the requirements section, a prioritized listing of factors must be developed to aid the design team in the tradeoff and decision making process. This collection of priorities is known as the design philosophy.

While developing the design philosophy, initial thought is occurring on the types of technology and elements that we believe need to be placed on the ship to meet the aggregate of capabilities desired. This process includes drawing from the design team's experience base, researching design innovations in the literature, and examining existing equipment that may be suitable for inclusion on this ship. Some of the design innovations considered/desired are included in section two of this chapter.

This process culminates in the development of an element selection list, which is included in the third section of this chapter. The items on the element selection list are then examined, weighted, and judged to determine the elements that we believe will be most suitable for this ship design. It is not until after further stages of design effort that all of the elements can be deemed feasible.

A. DESIGN PHILOSOPHY

This design philosophy provides a prioritized listing of factors used in guiding design tradeoff decisions during all phases of the RDS-2010 design process. The factors selected and their relative weighting were governed by the *Requirements Document for RDS-2010* (Section II.B).

This design philosophy is intended for use exclusively by members of the RDS-2010 design team in determining tradeoffs and selections of design alternatives. Other uses or applications of this document are beyond the scope of its intent.

Specifically, the Range of Capabilities Desired and General Affordability Limits (Sections II.B.4 and II.B.5), lead to the following list of prioritized factors:

- 1. Cost, Acquisition**
- 2. Combat System, Defensive**
- 3. Vulnerability**
- 4. Manning Reduction**
- 5. Combat Capability, Offensive**
- 6. R, M & A**
- 7. Appearance**
- 8. Signature/Detectability Reduction**
- 9. Standardization**
- 10. Upgradability**
- 11. Sustainability**
- 12. Environmental Impact**
- 13. Future Growth**
- 14. Habitability**

Discussion:

(1) *Cost, Acquisition* - this factor ranked number one due to the severe budgetary constraints this ship must be designed and built under. Failure to account adequately for cost savings as a prime objective will most probably kill this project during the DOD and congressional approval levels of review. Cost is listed explicitly instead of some indirect parameters such as length, beam, draft, or displacement since cost control is the factor actually desired. Some may regard placing of the cost factor ahead of a military capability such as defensive systems as untenable, but it merely recognizes the reality of the current environment.

(2) *Combat System, Defensive* - also known as hard and soft kill capability, this feature addresses one portion of the susceptibility equation. The ability to defeat an incoming threat is of paramount importance for decreasing the vulnerability of this ship. This capability should be considered essentially equal with cost reduction in importance.

(3) *Minimizing Vulnerability* - once the ship is hit, minimizing this ship's vulnerability ranks high in importance due to the ship's mission requirements. Operating close ashore in unstable world regions greatly increases the likelihood of unexpected, close aboard attack.

(4) *Manning Reduction* - in concert with minimizing ship's vulnerability and reducing acquisition cost, adequate consideration will be placed on minimizing ship's manning consistent with mission needs, available technology and damage control requirements. Manning reduction is primarily achieved through automation of functions in all aspects of ship operations including ship control, engineering plant operations, and war fighting operations. Design decisions to automate functions to reduce manning requirements will reduce vulnerability if all aspects of the vulnerability equation are properly taken into account. The largest counter point to reduced ship's manning is the impact on damage control capability. Present design and practice makes damage control operations 100% manual (hence, manpower intensive). Failure of current ship designs to take advantage of the technological innovations which could supplant or enhance the requirement for a crew member involvement in damage control operations may prove to be as significant a driver on crew size as watch, quarter, and station bill requirements. The salient point remains that merely automating operating stations and maintenance functions will not necessarily alleviate the crew requirement if active measures are not taken to address the requirements driven by damage control teams and damage control concepts.

(5) *Offensive Combat Capability* - the RDS-2010 is not a major offensive strike platform, though any offensive capability which enhances the utility of the ship above and beyond the ship's tactical land strike mission requirements commensurate with the previous factors should receive consideration.

(6) *Reliability, Maintainability, and Availability (R, M & A)* - these design attributes are considered more important than the related areas of standardization, upgradability and sustainability, due to their impact on ship mission attainment and synergistic impact on manning reduction. Specifically, this ship's requirement to operate independently for sustained periods of time (no external maintenance support) make the reliability, maintainability, and availability of ship's equipment paramount.

(7) *Appearance* - the requirement of this ship to "show the flag" and perform the role of "presence projection" make design decisions affecting ship appearance a moderate attribute to be considered. Strong consideration should be made for design attributes which improve the "war fighting" appearance of the ship without excessive negative impact on the previous factors.

(8) *Signature/Detectibility Reduction* - ranked considerably lower than the other half of the susceptibility equation (defensive capability), these design features are not as important when taken in context with the ship's mission and probable operating theaters. Any design attributes which improve this factor without impacting previous factors should be considered, however.

(9) *Standardization of shipboard components* - since these features tend to drive up design and acquisition costs with little improvement in capability, this is not ranked high. This is a desirable attribute in cases where it can be obtained without disproportionate costs increases or in cases where it would dramatically improve aspects of R, M, & A.

(10) *Upgradability* - this factor which is the ease of implementing improvements to existing systems is driven by accessibility and the system architecture. It is desirable but not enhancing to the ship's mission.

(11) *Sustainability* - enhancement above baseline design requirements for ship's sustainability should only be considered if they do not negatively impact previous factors.

(12) *Environmental Impact* - enhancements beyond regulatory requirements are of lesser importance than other factors.

(13) *Future Growth* - design attributes that enhance the ease and capability for addition of new systems impacts original system architecture and architectural design margins. This capability is not considered important in view of the ship's small size and mission.

(14) *Habitability* - embellishment of ship's living spaces are inconsistent with mission requirements and stated design goals of decreased vulnerability and increased R, M, & A. Embellishments include features such as false bulkheads and overheads, wall and floor coverings chosen for cosmetic purposes and any other features which would enhance the spread of fire, toxicity of smoke, impede or obscure access to equipment, cabling, ventilation ducting, piping or other ship's systems. Aspects of habitability which would benefit crew morale should be considered and primarily include the allocation of adequate living space for each individual and the capability of the individual to control the environment of their living space.

B. CONCEPTIONS AND INNOVATIONS

During the early phases of any design process there are many ideas which are considered. The length of consideration may be limited to a few seconds or it may be extended through long discussions while determining what must be incorporated into the design. This section addresses some major ideas which the design team considered worthy of inclusion. The absence of a particular item from this section does not necessarily mean that it was overlooked or deemed unimportant. While some concepts were envisioned and dwelt on at great length, time and resources did not always permit the effort to proceed to as detailed level as would have occurred in industry.

1. TOTAL SHIP INNOVATIONS

Extensive use of computers throughout the ship will smooth the flow of data and information and automate many low level routine tasks. Personnel will serve in a supervisory role to monitor the "system". Multi-purpose interface consoles will be used to the maximum extent possible in *all* system interface capacities. These would include a software driven interface with touch sensitive screens. Essentially, any system function will be available from any interface terminal with appropriate access control. This allows for easy system upgrade without requiring changes in hardware consoles and associated interface cabling.

Ship maneuvering functions will be controlled automatically. Tracks will be entered at the navigation console and controlled through an auto pilot. The auto pilot will be linked to the combat system for proactive defensive maneuvers and collision avoidance. Roll stabilization can also be incorporated through the use of the rudder.

A survivability management system will be used to smartly reconfigure systems in anticipation of a weapon hit and provide proactive damage control to minimize the spread of secondary damage.

2. COMBAT SYSTEM INNOVATIONS

The ship's radar cross section is critical to the performance of the ship's defensive posture. The use of signature reduction technology in designing the ship's structure will significantly reduce detection ranges by redirecting incident energy away from the source. This enhances the effectiveness of decoys thus reducing susceptibility. As designers we can incorporate these ideas into our design by canting the ship's structure and providing storage compartments flush with the superstructure to remove topside clutter.

We envision a completely integrated combat system which includes all warfare areas. Each piece of equipment will be connected through a redundant, fiber optic multi-ring data bus. This will centralize information flow allowing any system to easily access the appropriate data on the bus. This will greatly improve the flexibility, survivability and upgradability of the system.

A Built-In Test and Evaluation module will be installed in every system to aid in minimizing system down time caused by failures and damage to system components. This would interface with another higher level system module, and by using System Readiness Logic provide up-to-date system status to operators. This would also provide a means to reconfigure the system for maximum combat readiness as required by tactical situations and doctrine planned into the software.

This ship has an expected life of 40 years. Historically, combat systems have been replaced every decade. Modular system design will be emphasized for ease of replacement, interface compatibility and for reduction in the cost associated with overhauls.

3. AFFORDABILITY FEATURES

Affordability was at the top of our design philosophy. Although production cost is only a small percentage of the overall acquisition cost, advanced production concepts will be used to achieve cost savings. This can be accomplished by reducing the cross

boundary interface between production modules and minimizing the use of compound curvature requirements in steel work. Building zones need to be established early on so that the ship can also be built more efficiently.

In order to improve ship readiness for lengthy deployments we must improve the current maintenance philosophy. Designing this ship for a 15 year overhaul cycle and incorporating condition based maintenance should reduce system down time on patrol and improve operability. This statistically based replacement program will be accompanied by various new test methods in order to overcome some of the pitfalls experienced by the current generation of preventive maintenance. This process may incur a higher ship acquisition cost but will be significantly offset by a reduced life cycle cost. Standardization of components will also synergistically benefit the total ship through greater availability of parts and the requirement to stock fewer parts.

4. SURVIVABILITY FEATURES

Survivability features are integral to this design. The standard concepts considered to reduce the ship's susceptibility to a weapon's hit are threat warning, noise jamming and deception, signature reduction, threat suppression, use of expendables, and equipment to support the use of tactics. The standard concepts considered to reduce the ship's vulnerability are component redundancy or elimination, component location and/or shielding, passive damage suppression, and active damage control. Reduced manning also lowers the likelihood of casualties and reduces vulnerability. While manning reductions require additional acquisition investment for automation, there is a significant reduction in life-cycle cost associated with personnel. Designing with redundancy, the equipment capable of performing the same task, and enclaving together all equipment necessary for proper operation of that system will improve the damage tolerance of this design. This will be discussed in greater detail later.

A double hull design concept has great merit for the shell of this ship. The primary purpose of using a double hull is to reduce vulnerability. The significant addition of reserve buoyancy improves the ability to "FIGHT HURT". The inherent strength in the double hull design allows for reduced scantlings due to the higher section modulus, thereby reducing cost. The between skin distance will accommodate the latest in programmable welding technologies and provide for ease of inspection and maintenance.

5. PROPULSION PLANT VISION

From the results of several studies that have been done on modern propulsion systems, we determined that the Integrated Electric Drive was superior from the perspective of survivability, reduction in total weight of the propulsion system, and ease of arrangement. The flexibility associated with arrangements would also reduce the vulnerability of the propulsion system. Since shallow water operations pose a higher likelihood of propeller damage, a controllable reversible pitch propeller is not considered the best candidate. The integrated electric drive combines well with the fixed pitch propeller because each reversible propulsion motor has a full range of speed control.

Combined diesel electric and gas turbine propulsion has many advantages as well. Although the specific weight and volume of this system is higher than a conventional gas turbine system, the fuel efficiency at patrol speeds could justify consideration due to reduced fuel payload.

6. ELECTRIC PLANT VISION

Using today's technology ship service electric power can be generated from the variable frequency propulsion generators using solid state power converters. This power will be distributed throughout the ship using a ring bus, and each system will provide for its own specific voltage and frequency needs from the main power grid. Power management will be controlled automatically with smart load shed coordination with the

combat system. System reconfiguration due to degraded capacity will be performed automatically to maximize available power consistent with the ship's tactical situation.

C. ELEMENT SELECTION OPTIONS

Table 3-1 lists the element selections that resulted from our study of design innovations and available equipment for inclusion on the ship. In some categories, there are multiple choices which must be winnowed out during the early phase of the design process. Other categories list only a single item, indicating our conclusion that this item is required for inclusion on the ship.

Using the Element Selection List, a lengthy search was conducted for data pertaining to the specific elements. This data, when available, was used for performing detailed comparisons of functional capabilities and physical parameters. Appendices B and C contain some of the relevant portions of that study. In Appendix B, page one, the *Payload Selection Matrix* is shown. This matrix includes all of the elements considered by mission warfare area. For the proposed ship there are several cases where two closely related alternatives exist for some of the elements under consideration. Option 1 and Option 2 are described in chart form for a quick comparison. In rows two and three the elements which were selected based on the various decision matrices are listed. The pertinent decision matrices which led to those conclusions are included in Appendix C.

Table 3-1. Element Selection List.

- A. HULL
 - 1. Type
 - a. Single/mono
 - b. Double/mono
 - 2. Collective Protection System
- B. MECHANICAL
 - 1. Plant type
 - a. Diesel engines
 - b. Gas turbines
 - c. Combined diesel and gas turbine
 - d. Combined diesel or gas turbine
 - 2. Reduction gear
 - a. Mechanical (reversing, w/clutch)
 - b. Direct shaft coupled
 - c. Electric drive
 - d. Mechanical (non-reversing)
 - 3. Propeller
 - a. Variable pitch
 - b. Controllable and reversible pitch
- C. ELECTRICAL
 - 1. Generator system
 - a. Diesel
 - b. Gas turbine
 - c. Propulsion derived
 - 2. Distribution system
 - 3. Power management system
 - 4. Emergency power system
- D. COMBAT SYSTEMS
 - 1. Detection/sensors
 - a. Air: SPS-48/49/IFF, Low budget phased array
 - b. Surface search: SPS-67 family
 - c. IR search: SAR-8
 - d. ESM: SLQ-32(V)3
 - e. Sonar: High resolution hull and remote, SQS-53 (low budget)
 - f. LAMPS III
 - g. Aconatic intercept: WLR-9, SRS-1 (Combat DF)
 - h. Mk 23 (TAS)
 - i. KAS-1 (CWDD)
 - 2. Command and decision
 - a. NTDS (Link 11)
 - b. WSA 423 C&C
 - c. ACDS
 - 3. System information coordination
 - 4. System readiness coordination
 - 5. External communications: WQC, HF, UHF, VHF, SATCOM, JITDS, JOTS
 - 6. Interior communications
 - 7. Weapon control
 - a. Mk 92 FCS
 - b. Mk 91 FCS
 - 8. Navigation
 - a. Furuno, LN-66, SPS-64
 - b. GPS, SATNAV
 - c. TACAN
 - d. WRN-5,
 - 9. Engagement/weapons/countermeasure
 - a. Missile/Point defense: RAM, NSSM, SM-1/2, CIWS Mk 15, Goalkeeper, Stinger missile turret
 - b. Gun: 5" -54 cal Mk 45 gun, Mk 24 TDT, OTO 76mm gun, 25mm Chain gun, 7.62mm mini-gun
 - c. Torpedo: SVTT Mk 32, Mk 50
 - d. Depth charge system: RBU/Hedgehog (upgrade)
 - e. Tomahawk VLS/Harpoon
 - f. CM: Mk 38 decoy launcher, SRBOC, LAD Chaff, 3" rocket decoys
 - g. Anti-torpedo defense: Talisman, Nixie, NAE, ADC, CSA
 - 10. Remote vehicle mine hunter/avoidance

The second page of the *Payload Selection Matrix* (Appendix B) includes all of the elements considered by equipment categories. Page two of Appendix B contains all equipments/systems considered whereas page one only lists those associated with a specific warfare area. This step of the process addressed the elements, but not the quantity or arrangement of them. The intent is to determine the most cost effective (dollars, weight, area, etc.), yet capable equipment/system to meet the required capabilities as delineated in the CNO Tentative Requirement Statement. When two elements under consideration had a wide host of utility factors for comparison, it occasionally seemed appropriate to have a second alternative based on factors such as cost, weight, political mood, logistical commonality. The combat system elements have undergone a preliminary threat evaluation consisting of four diverse scenarios. This threat evaluation is presented in the next chapter as part of the Combat System Definition. The reasoning for the decisions which were agreed upon by the design team are described below, supported by Appendices B and C.

1. HULL

a. DOUBLE HULL vs. SINGLE HULL

Major issues: Passive protection, survivability, displacement, and cost

Minor issues: Ease of arrangement and producibility (ease of fabrication)

Proposed is the advanced double hull design (ADHD) concept which consists of two shells connected by longitudinal web girders and floors. Simply put, it will resemble the corrugated design used in designing high toughness, high strength cardboard boxes. Transverse frames and longitudinal stiffeners can be eliminated because of the inherent strength achieved by the cellular concept. Benefits include reduced vulnerability in the event of a hull impact, higher hull girder stiffness based on higher section modulus and greater producibility (easier to fabricate, insulate, outfit, and paint) with a projected cost savings of 8-12% now with further savings inevitable during maintenance periods. The

between skin distance will be large enough to accommodate the latest programmable welding technology and to provide for ease of inspection, maintenance and preservation.

Disadvantages: 1% increase in displacement for the double hull design.

b. Collective Protection System

First option is to install a full collective protection system. Based on total ship impact (cost, weight, etc.), the system may be degraded to include two or three zones. This concept dovetails with the intent to enclave the ship into three to five enclaves. Ideally, each enclave will have collective protection, though if this becomes unreasonable from a size and weight (and thus cost) point of view, then selective collective protection sub-enclaves will be considered. Primary focus will be to maximize the mission readiness of the ship when collective protection zones are detailed.

2. MECHANICAL

a. Plant Type (Including Transmission)

Several exhaustive studies have been conducted in order to determine the optimum power plant for destroyers and frigates [Ref. 1, 2, 3 and 4]. The term power plant here is used to include both propulsion and electrical plant. Factors addressed in these studies included:

- (1) Propulsion and Electrical Plant Weight
- (2) Propulsion and Electrical Plant Volume
- (3) Power Plant Survivability
- (4) Sustained Speed Margin
- (5) Ship Top Speed
- (6) Ship Detectability
- (7) First Cost (Power plant)
- (8) Life Cycle Cost (Power plant)
- (9) Crew Size (Engineering)

- (10) Energy Consumption
- (11) Ship Displacement & Volume
- (12) Ship Operability (Ease of Control)
- (13) Complexity
- (14) Standardization of Components
- (15) Technical Risk

Evaluation criteria included many factors. The *initial cost factor* had highest priority. *Risk* and *standardization of components* had low priority in one of the studies. All of the other factors had medium priority. All of the studies showed that mechanical drive systems were inferior to the electric drive system options based primarily on weight and ease of arrangement. Some of the combined diesel and gas turbine systems had low energy consumption rates, though they were not rated well overall. A medium speed diesel may have an efficiency as high as 46% while a gas turbine has an efficiency of about 35%. On the other hand, a medium speed diesel may have a specific weight of 25 lb/HP, while the gas turbine specific weight is 3.5 lb/HP. These two factors give just a brief glimpse of why a very thorough study such as [1] is needed. Primarily, this study was used to determine which propulsion plant was optimum for this new ship class. The innovative and expensive podded propulsor seemed to be optimum in some cases, but considering that the low cost RDS 2010 must be capable of operating in mine infested shallow waters it does not seem a worthy candidate for this ship design. In order to obtain a balanced total ship design, a second propulsion plant candidate may have to be considered. The two options are addressed below.

(1) Option 1: Gas turbine integrated electric drive system

System consists of multiple propulsion gas turbines generators (PGTGs) supplying a propulsion power bus. Additional smaller gas turbine driven generators may be needed for efficient low speed cruising conditions. Ship's electric power

needs will be derived from the propulsion bus via solid-state power converters. This system allows maximum flexibility in machinery plant layout to allow dispersion of components within the hull to decrease ship vulnerability.

(2) Option 2: Combined diesel electric and gas turbine electric drive

This combined diesel electric and gas turbine electric drive (CODLAG) system has the potential of increased plant efficiency at low cruising speeds based on a lower specific fuel consumption (lb/hp-hr), yet still provides the flexibility in machinery plant arrangement that is available with gas turbine electric drive. Additionally, this system may lead to smaller volume/fewer intakes and uptakes. The disadvantage of this system would be higher specific volume (ft³/hp), specific weight (lb/hp) and initial ship cost (\$).

b. Propeller - Variable Pitch vs. Controllable Reversible Pitch (CRP)

This decision is based on :

(1) the fact that the electric drive motors are reversible and have full-range speed control; and

(2) shallow water operations pose a higher likelihood of propeller damage, making a CRP propeller too high a risk (not robust enough).

3. ELECTRICAL

a. Generation Scheme

Electric power for either option will be derived from the propulsion power bus via solid-state ac-ac power converters.

b. Distribution system

The propulsion power bus will be a standard ring bus configuration for maximum flexibility and reliability. It is not perceived that propulsion power will be distributed to portions of the ship in which it is not required. The load power bus will also be a ring configuration. The electric loads will be supplied from solid-state power

converters located in each enclave, with redundant capability to supply other enclaves (and vice versa).

c. Power management system

Power management will be controlled automatically with smart load shed coordination with the combat system. System reconfiguration due to degraded capacity and capability will be performed automatically to maximize available power consistent with ship's tactical situation. Deriving the ship's service electrical power from the propulsion generators allows the capability to momentarily divert all propulsion power from propulsion to ship's service to support critical combat systems operations during system reconfiguration.

d. Emergency power

There will be no dedicated emergency power system, though generator sizing and quantity will allow sufficient capacity for some generation capacity to remain in standby during full load conditions.

4. COMBAT SYSTEMS

a. Detection Systems/Sensors

(1) Air Search Radar

Several studies were performed comparing the SPS-48, SPS-49, Mk 92, and a Low Budget Phased Array (LBPA) radar systems. The LBPA is envisioned to be of the Aegis style, yet with reduced capability and cost. The system characteristics, weight and cost were compared and weighted so that cost and weight were of primary importance. Summaries of the analyses are included in Appendix C under the heading of *Primary Air Search Sensor Matrix* and *Secondary Air Search Sensor Matrix*.

(a) *Option 1:* Primary: SPS-49 Secondary: Mk-92

(b) *Option 2:* Primary: SPS-49 Secondary: SPS-48

(2) Surface Search Radar

The SPS-67 will be employed as the primary surface search radar with the primary navigation radar, the SPS-64, as the backup.

(3) IR Search

The SAR-8 will be used for infrared detection and tracking.

(4) ESM

The SLQ-32(V)3 will be used.

(5) Sonar

(a) The SQS-53 (low power/low budget) hull mounted sonar will be used. The Kingfisher mine hunting adjunct to the SQS-53 will be available before letting of the contract, so the technical risk in this area has diminished significantly. One concern, however, is that the SQS-53 sonar in general is too powerful in omni-directional and Sector Search modes for shallow water ASW missions, which is its primary purpose. However, a localization mode by beam steering could be used in shallow water with only minor degradation. A variant needs to be designed which will allow omni directional operation at low power.

(b) The Light Airborne Multi-Purpose helicopter (LAMPS III) will be the primary off hull sonar system for submarine detection and targeting with the Unmanned Undersea Vehicle, UUV, as the primary off hull mine hunting sonar system. The UUV is under risk of being dropped from the RDS 2010 class because of its high cost and low mission utility for the expected threats.

(6) Acoustic Intercept Receiver

The WLR-9 will not be used for detecting incoming torpedoes, since this function is inherent to the surface ship torpedo defense system (SSTD).

(7) Chemical Detection System

The KAS-1 chemical warning directional detector will be used.

b. Command and Decision

An integrated Command and Decision system will need to be designed around the specific elements of the combat system.

c. System Information Coordination

An integrated System Information Coordination system will need to be designed around the specific elements of the combat system.

d. System Readiness Coordination

An integrated System Readiness Coordination system will need to be designed around the specific elements of the combat system.

e. External Communications

The communications suite will consist of the following types of equipment to perform the functions currently done by underwater telephone, HF, UHF, VHF, and SATCOM transmitters and receivers. Additionally the suite of COPERNICUS architecture will include JTIDS, JOTS and SSES capabilities. It is conceived that these elements will be housed in panels, enclaved throughout the ship and that a radio room as we know it today will not exist. Data links for ship-ship and ship-shore data transfer will also be required.

f. Interior Communications

The interior communications system will consist of a fiber optic digital multiplexing system for voice and data distribution and traditional sound powered phone circuits for robust, damage control voice communications.

g. Weapon Control System

An integrated Weapon Control System will need to be designed around the specific elements of the combat system.

h. Navigation System

The navigation system will consist of SPS-64 as the primary radar system, and the Furuno as the backup radar system. TACAN will be required as helicopter support. A study of this mission area was performed and is included in Appendix C as the *Navigation Radar Matrix*. Although the SPS-64 did not rate as well as the LN-66 or the Furuno overall, it was chosen as the primary navigation radar since it can send data to the fire control system and serves as the backup to the SPS-67 in the ASUW mission area. The Furuno and the LN-66 radar are essentially commercial grade, low cost navigation radars with no capability to be interfaced with the ship's combat system. They are useful in providing a low-cost navigation backup capability, however.

i. Engagement/Weapons

(1) Long Range Intercept Missile

The SM-1/2 family of missiles will be used for long range intercept of air and surface targets. The *Missile Selection Matrix* in Appendix C shows how the candidate's ratings compared.

(2) Short Range Intercept Missile

The RAM (RIM-116) series of missiles will be used for short range intercept of airborne targets.

(3) Anti-ship Missile

The Harpoon missile will be used, including the upgraded IR version of Harpoon, the Sea Launched Attack Missile (SLAM) version.

(4) Point Defense system

The Phalanx (MK-15) CIWS will be used for ultra-short range airborne target intercept. The *CIWS Selection Matrix* in Appendix C shows how the candidate's ratings compared.

(5) Naval Gunfire Support

(a) Option 1: The 5"-54 Mk-54 medium caliber gun provides a higher weight round and slightly improved range over option 2, but has a lower firing rate and double the weight. Use of the autonomous Naval strike round (ANSR) has the potential of increasing range to 50 nm, however at a significant cost increase per round.

(b) Option 2: The 76 mm Oto Melara medium caliber gun provides higher firing and training rates, but the round weight is one-fifth the weight of a 5" round. The *Medium Caliber Gun Selection Matrix* in Appendix C shows how the candidate's ratings compared.

(6) Small Caliber Gun

(a) The 25 mm Chain gun will be used.

(b) The 7.62 mm minigun will be used.

(7) Land Strike Missile

The Tomahawk Land Attack Missile (TLAM) will be used. With the system installed, it will be possible to use the Tomahawk Anti-Ship Missile (TASM).

(8) Anti-Torpedo Defense

The new Surface Ship Torpedo Defense (SSTD) system will be used.

(9) Torpedo

The Mk 50 Barracuda torpedo will be launched from the SVTT Mk 32 torpedo tube by the Mk 116 Fire Control System or a new fully integrated fire control system. In addition, the LAMPS helo has the capability to launch torpedoes.

(10) Depth Charge/Mortar System

The Soviet RBU-6000 and the antique US Hedgehog mortar systems are very heavy (30,000 lb loaded launcher) and would impose a significant impact on the RDS 2010. The need for this type of system still exists based on the fact that a

Mk 50 torpedo acquisition of an enemy submarine in shallow water has a lower than desired probability. A new light weight launcher is necessary since the Hedgehog is limited in range to 270 yards and a submarine's location could likely be determined at a longer range. Ideally, the LAMPS or UUV will assist in locating the submarine and the integrated fire control system would launch mortars aimed at a specific coordinate and set to explode at a designated depth. It is recommended that OPNAV assign a study group to determine the usefulness of deploying this type of weapon against submarines in shallow water.

j. Countermeasures

(1) ECM

(a) Based on the perceived threat, all of the countermeasures which were considered will be used and launched using the Mk 36 Super Rapid-Blooming Chaff (SRBOC) Launcher. These included Launched Active Decoy (LAD), SRBOC, and TORCH. These expendables will provide protection against missiles with active and passive radar and infrared homing systems. Most of the new countermeasures currently being developed will be launchable with this launcher.

(b) The SLQ-32(V3) provides ECM capabilities.

(2) Sonar Acoustic

The outdated Talisman and Nixie were compared and found to be similar except Nixie weighs 50% less. Additionally, the new Surface Ship Torpedo Defense (SSTD) will be operable by the year 2000. This system contains both active and passive defense measures and will be used on the RDS 2010 instead of the towed noisemakers and launched submarine style noisemakers (ADC, CSA and NAE).

IV. FEASIBILITY STUDIES - COMBAT SYSTEM DEFINITION

The next phase of the design process is defining the combat system. This is the first part of performing the feasibility studies. Since the combat system represents a major payload of the ship, the determination of the specific elements chosen for the combat system is required to proceed on with the Hull, Mechanical, and Electrical Feasibility Studies. The size, weight, location, power and other auxiliary service requirements of the payload, when combined with the performance requirements of the ship, will in many respects define the ship's HM&E characteristics.

Final selection of the combat system elements which comprise the combat systems suite of the RDS-2010 is an iterative process of selecting candidate combat system elements and then evaluating their ability to defeat threat weapons in plausible threat scenarios. Based upon the results of the threat scenario evaluation, adjustments can be made to the combat system elements. In addition, the minimum number of engagement elements are determined from the threat scenario evaluation.

In this chapter, the threats are first defined. Plausible threat scenarios are then presented to evaluate the ability of the candidate combat system elements chosen in the last chapter. Based upon this evaluation and the ability of the combat system elements to defeat the proposed threats, the minimum number of combat system elements can be chosen in the context of defeating the threat in the specified scenarios. This determination of number of combat system elements does not include the consideration of redundancy for reliability or survivability reasons.

A. THREATS

A survey was completed of the current threat weapon inventory using Naval Postgraduate School library resources. Based upon this survey, a number of threat weapons were developed that were felt to be similarly challenging as the actual threats.

This procedure, however, allowed the design team to keep this portion of the design process unclassified. Table 4-1 lists the threats that will be used to determine the combat system performance for the RDS-2010.

TABLE 4-1. RDS-2010 THREAT WEAPONS.

AIR/SURFACE/SUBSURFACE THREATS							
Type	RPS 2010 Designated Enemy Name	RADAR Cross-Section (m ²)	Speed (mach)	Range (nm)	Warhead Yield (kg)	Guidance	Profile Trajectory
Missiles	THRASHER (A-S)	0.013	2.5	40	10	Passive Radar	Homes on Radar
	TAKEOVER (A-S)	0.7	3.4	300	1000	Active or Passive Radar	High Alt. w/50° terminal dive to target
	SEAGULL (S-S)	0.22	0.7	15	110	IR	15 meter sea skimmer
	SUNSTROKE (S-S)	0.1	2.5	65	450	Active Radar	10 meter sea skimmer w/1° dive
Subsurface	Small Mines	R-1 ft.				Various	
	Mk48		35 kts	35 ktyds			
	Spearfish		70 kts	18 ktyds			

B. THREAT SCENARIOS AND EVALUATION

In this section, the threats are combined with likely engagement actions to form plausible engagement scenarios. The scenarios consist of specified threat weapons launched at the ship. The number, range, and bearing of the threats were picked to match likely encounters in the suspected operational area in which this ship will be patrolling.

Due to time and resource constraints, only four AAW scenarios were evaluated. In actuality, additional scenarios would have to be developed and evaluated in the other warfare categories (ASUW, ASW, and mine warfare).

One of the most challenging defensive capabilities of the RDS-2010 ship is the defeat of the Anti-Shipping Missile (ASM) threat. Conflicts within recent memory have proven the effectiveness and lethality of the ASM threat, including the susceptibility of warships to damage. The solution to Anti-Shipping Missile Defense (ASMD) demands a mix of

defensive concepts, including such hard kill weapons as missiles, guns and high-energy directed energy weapons be deployed in addition to other defensive systems such as ECM, ECCM, and decoys. Note that the success of these types of ASMD systems requires an overt and explicit effort in applying the techniques of vulnerability reduction to the ship to reduce its susceptibility to damage by ASM debris at the mission or firepower kill levels. Also, success of the ASMD system chosen for the ship requires the adoption of tactical plans and procedures tailored to the changing ASM threat.

The ASMD elements chosen for the RDS-2010 include:

- ▶ Missiles - SM-1/2 and RAM
- ▶ Guns - Mk15 Phalanx and Mk 45 5"/54
- ▶ ECM - SLQ-32 (V3)
- ▶ CHAFF

This section presents the results of the study of four diverse Anti-Air Warfare (AAW), defensive threat scenarios (specifically, ASMD) and is to be used in conjunction with the previous chapter's section on element Selection Options. Specifically, this section is used to determine and validate choices for the minimum number of missiles, types of missiles, guns, and close-in protection systems required to separately defeat the four surmised threat scenarios. Modifications to these quantities may and probably will occur as the design progresses. The threat ASMs used in these scenarios were defined in the previous section of this chapter.

Only AAW threat scenarios are presented. This does not imply that the ASW, ASUW, or mine-countermeasures are not important or not in need of study. Resource and time constraints, however, preclude similar studies in these defensive areas. The basic methodology present in this report would also be used to study these other defensive warfare areas, however.

1. Background Development

Performance of ASMD analysis, the ability to defeat an attacking ASM, is normally expressed in terms of the ability to protect the defending ship from damage. The acceptable level of ship damage is not well defined yet, though for the RDS-2010, this is considered a severe constraint. Emphasis is placed on defeat of the ASM threat vice accepting resulting damage from a "leaker".

In general, the capability to defeat a target is expressed as:

$$P_k = P_S = P_{SD} \cdot P_D + P_{SND}(1 - P_D) \quad (4-1)$$

where:

P_k = probability of target kill (or defeat),

P_S = probability of ship survival at the kill level of interest,

P_{SD} = probability of ship survival given that the ASMD system causes damage to the target,

P_{SND} = probability that the ship will survive given that the ASMD system does not damage the target (i.e., the inherent survivability of the ship), and

P_D = probability that the target is damaged.

Clearly, (4-1) implies an assessment of the RDS-2010 ship survivability is inherent in quantifying a weapon's system capability to defeat the ASM threat. This is not included in this report, though a goal of "zero hits" for the RDS-2010 is desired in response to the *Requirements for Regional Deterrence Ship (RDS) 2010* (Section II.B).

The ASM defensive range can be roughly divided into three zones as depicted in Figure 4-1. The long range defensive system for the RDS-2010 is the SM-1/2 and associated Fire Control System (FCS). In the long range intercept game plan, the ability of the ASM to penetrate to the vicinity of the ship after intercept by the long range system is indicative of a lack of a kill. Indeed, standard practice criterion for long range system target defeat is not only ship protection, but damage to the ASM such that ship protection

is guaranteed to the point where no further weapons must be addressed to the target in question. This kind of damage requirement is used to conserve expensive and volume consuming long range weapons by allowing the FCS or kill assessment system to identify a target kill and address the next weapon to the next most threatening target.

Figure 4-1. ASM Defensive Range

For short and medium range systems (SM-1/2 and RAM), the observable kill[□] criterion does not apply. Evaluation of systems tests versus flying targets indicate that five to fifteen seconds are required in many cases to allow positive identification of a target kill, even under the classic catastrophic kill level. This means that for medium to short range systems, this time delay in kill identification may defeat the purpose of requiring observable kills. The defensive missile time-of flight (TOF), when coupled with the target speed, results in a very short second encounter requirement. Clearly, a shoot-shoot-look

[□] An observable kill is any damage to the ASM. Note that the characteristics of target reaction which is *observable* to the FCS or weapons assessment system is a function of the system performance criteria. For this reason, a more conservative evaluation of the required target damage observable to the kill assessment system is the *catastrophic kill* level (described as the classic nearly instantaneous breakup of the target).

engagement scenario is required in this situation. The required level of target damage produced for medium-to-short range encounters is considered to be at the catastrophic kill level.

For very short range ASMD (often known as "last-ditch" effort), the RDS-2010 employs the MK15 Phalanx system. In this scenario, even catastrophic target damage may not always protect the ship. Issues such as target speed, mass, and ship-to-target geometry at ranges under one nautical mile often couple to result in some level of ship damage from the debris of the destroyed ASM. Indeed, for very short range systems, the assessment of likelihood of own ship survival takes on a new meaning. The system must damage the incoming ASM such that either (1) it misses the defending ship by such a distance that upon water impact the air and water shocks produced by detonation of the warhead result in low probability of ship damage; or (2) target breakup occurs at such a range that the resultant particles either can not reach the ship or do not have a significant capability to produce ship damage upon impact.

The focus of this section of the report is the determination of *hit* and *kill* probabilities of incoming threats with the weapons systems employed on RDS-2010. The probability of hit, P_H , implies the likelihood that the kill mechanism or damage producing agent(s) employed by the defensive system interact with the target at some level of intensity. The actual methods to determine P_H by determining this level of intensity is beyond the scope of this discussion. Realize, however, that determination of P_H is comprised of inputs from such varied areas as target detection, tracking, fire control characteristics, pointing accuracy, weapon characteristics (ballistics, aerodynamics, etc.), reliability, maintainability, fuse characteristics, ECM environment, weather, target performance, and warhead characteristics. Fortunately, seldom do all these factors have to be considered simultaneously.

For the analysis conducted in this section, many gross simplifications are employed to allow solution of the problem with available data and techniques. The purpose of this phase of the design process is to delineate the basic analysis technique which is used for a "first-order" evaluation of the RDS-2010 combat system effectiveness against proposed scenarios. The remainder of the section is organized with a general procedural and calculation summary used for the analysis, followed by specific analysis of four threat scenarios. These scenarios were chosen to be representative of a diverse range of ASM threat situations that could likely be encountered based on the guideline contained in the *Requirements for Regional Deterrence Ship (RDS) 2010* (Section II.B). Finally, a summary of the results is presented with recommended weapon types and load out with supporting combat systems elements.

a. Assumptions

Of general note, the inbound target is assumed to be non-maneuvering, with exception of the terminal flight phase prior to impact. Also, a target hit is considered a kill.

(1) Radar Horizon

For the scenarios considered a conservative assumption is made that the radar horizon is 15 nautical miles at the surface. The radar horizon equation is given by:

$$rh = 1.667(\sqrt{H_{target}} + \sqrt{H_{radar}}) \quad (4-2)$$

where: rh = radar horizon in nm,

H_{target} = height of target above surface in feet, and

H_{radar} = height of own radar above surface in feet.

Assuming a target height of zero feet and a 15 nautical mile radar horizon, (4-2) is solved for an own ship radar height of 81 feet. This is the minimum height for the surface search radar.

(2) Operational Arcs.

The ship's weapon and sensor systems are assumed to have a 360° clear arc of fire and detection capability^o.

(3) Combat System Readiness

It is assumed that the combat system is in a full readiness condition.

b. General Scenario Rules

To ascertain whether a particular threat can be engaged, the following ground rules are used:

(1) A minimum ten second time delay is assumed from time of detection to time of engagement. This time delay accounts for the lag in:

(a) processing and passing information from the search radar to the Fire Control System (FCS);

(b) the illuminator locating the target and passing information to the FCS; and

(c) the operator intervention occurring prior to the Weapon Control System (WCS) automatically launching the long range engagement weapon. If the operator fails to intervene within the allotted ten seconds, the ship can still command destruct the weapon.

(2) A delay of four seconds is used from the time-of-kill assessment to the time of weapon re-engagement.

c. Analysis.

The following assumptions, equations, and values were used to calculate the probabilities of kill, the probabilities of hits, and the expected number of hits.^o

^o It is understood that the 360° clear arc of fire and detection, and the 15 nm radar horizon are assumptions that will require modification once the ship's superstructure has been defined.

^o The methodologies employed in this portion of the report are taken from a MIT Professional Summer Course entitled *Surface Ship Combat System Design Integration*, presented August 5-9 1991 at the Draper Laboratories in Cambridge, Mass.

(1) General

(a) Assume three basic self-defense systems are integral to the ship:

- (i) missiles,
- (ii) guns, and
- (iii) jammers/decoys.

(b) Assume an incoming missile will *not* hit the ship if and only if at least one of the defensive systems is successful (i.e., the threat weapon will function as designed and will hit the ship unless explicitly defeated by own ship defensive systems).

(c) For the probability formulations, the following events are defined:

- ▶ Let A be the event that the defensive missile is successful.
- ▶ Let B be the event that a gun system is successful.
- ▶ Let C be the event that the incoming missile is decoyed/jammed.

(d) The cumulative probability that at *least* one system is successful against each incoming missile is described in general by the cumulative probability formula given by:

$$P(\text{CUM}) = 1 - \prod_{i=1}^n (1 - P_k(i)) \quad (4-3a)$$

where: $P(\text{CUM})$ = cumulative probability of a kill by n kill mechanisms, and

$P_k(i)$ = probability that the i^{th} kill mechanism succeeded.

For the specific cases presented in this report with three kill-systems, the cumulative kill probability is given by:

$$P_{\text{kill,threat } i} = 1 - [1 - P(A)][1 - P(B)][1 - P(C)] \quad (4-3b)$$

where: $P_{\text{kill,threat } i}$ = cumulative probability of defeating the i^{th} threat,

$P(A)$ = probability that a defensive missile is successful,

P(B) = probability that a gun is successful, and

P(C) = probability that a jammer/decoy is successful.

(e) The probability that the ship will take a hit is given by:

$$P(\text{hit}) = 1 - \prod_{i=1}^n P_{\text{kill, threat } i} \quad (4-4)$$

(f) The expected number of hits is given by:

$$HT_{\text{exp}} = P(\text{hit}) \cdot m \quad (4-5)$$

where: m = the number of incoming threat missiles.

(2) Defensive Missile System Model

To determine the overall kill probability of the defensive missile system:

- (a) assume one incoming missile;
- (b) assume the defensive missile system has n chances (shots) at the incoming missile; and
- (c) assume each shot has a kill probability of p .

In this case, a kill is assumed if intercept occurs. The overall kill probability of the defensive missile is given by:

$$P_{\text{kill}}(A) = 1 - (1 - p)^n \quad (4-6)$$

(3) Defensive Gun System Model

To determine the overall kill probability of the defensive gun systems (Mk45 5"/54 and Mk15 Phalanx), the following general formulation is employed:

$$E_L = P_{kill}(A) = a \left\{ 1 - \prod_{i=1}^N [1 - P_L(i)] \right\}$$

where:

E_L = engagement effectiveness, (4-7)

a = System availability ,

N = number of rounds or bursts fired , and

$P_L(i)$ = single - round or burst effectiveness of the i^{th} round or burst .

In this report, the engagement effectiveness is assumed to be the same as the kill probability, though it really only implies that the fire control solution was adequate to place the round where it was needed, not that it actually got there. Additionally, system availability, a , is assumed 100% when needed.

(a) Overall kill probability of the defensive gun system is range dependent.

(b) Number of rounds fired is a function of:

- 1) firing rate (FR);
- 2) burst duration (T_{burst});
- 3) size of magazine (number of rounds available);
- 4) maximum pre-programmed burst duration.

Overall kill probability of the Mk 15 Phalanx Close In Weapons System (CIWS) is dependent on the specific target. Variables such as attack profile, speed, and Radar Cross Section (RCS) impact the kill probability. No easy analytic solution exists that reasonably approximates the kill probability for a general case. Based on physical flight parameters and profiles, the RDS-2010 ASM threats listed in Table 4-1 are assigned the kill probabilities listed in Table 4-2.

TABLE 4-2. ASM THREAT PHALANX PKILL.

<i>ASM Designation</i>	<i>Phalanx P_{kill}</i>
TRASHER	0.3
TAKEOVER	0.85
SEAGULL	0.7
SUNSTROKE	0.5

These probabilities assume the target is engaged the entire effective range of Phalanx (0.81 to 0.05 nm).

The 5"/54 Mk 45 Naval Gun Mount with Mk 86 Gun Fire Control System (GFCS) firing an IR fused round has a single shot kill probability against a missile that is approximated by:

$$P_{kss} = 0.5 \exp \left\{ \frac{-R^4}{5} \right\}$$

where: (4-8a)

P_{kss} = single - shot kill probability , and
 R = target range in nm .

A plot of (4-8a) is shown in Figure 4-2, which shows there is little reason to engage the 5"/54 gun on a missile target in excess of 2.5 nm range.

The engagement kill probability for the 5"/54 gun system would be given by:

$$P_{kill}(B) = 1 - \prod_{i=1}^n (1 - P_{kss}(n))$$

where (4-8b)

$P_{kill}(B)$ = overall gun engagement kill probability
 P_{kss} = single shot kill probability
 n = number of rounds shot during engagement

Figure 4-2. PkSS of 5"/54 Mk 45 Gun System with IR fused round.

(4) Jammer/Decoy System

The overall kill probability of the jammer/decoy systems onboard, $P(C)$, is a function of several variables, including:

- (a) equipment technical capabilities (hardware and software);
- (b) tactical employment of both jammer and decoy systems; and
- (c) environmental factors such as atmospheric conditions

including wind currents, air density, particulate content, humidity, etc.

For the purpose of this analysis the probability of the jammer/decoy systems obtaining a kill of the incoming threat missile is:

$$P(C) = 0.4 \quad (4-9)$$

The actual analysis to derive the number given by (4-9) is quite involved and beyond the scope of this report.

The scenarios are presented in a time line format, starting with time, $t = 0$ as the threat launch time, and positive values of time being the time of flight (TOF). The time line is run until all threats have theoretically impacted the ship. This method allows analysis of weapon system capabilities in terms of reaction times and capability of

engaging all threats until time of impact. In reality, this gives a worst case scenario, since running the problem to impact assumes no defensive system defeated the inbound threat. Sizing the number of weapons/launchers/guns and FCS supporting hardware on this figure would lead to an overly conservative design.

A more realistic evaluation is accomplished using the cumulative kill probabilities as TOF increases. This gives a kill probability for each threat for each defensive event undertaken in time. Using this technique, assessment can be made of reasonable kill probability as the threat event progresses; e.g., a 99.9% kill probability will be achieved with six defensive missiles launched. These time-event cumulative probabilities are included on the timelines. This methodology will lead to a more realistic weapon loadout requirement.

2. SCENARIO 1: Simultaneous launched high-altitude and sea skimming missiles

This scenario involves simultaneous launch of two threat missiles:

- ▶ *Takeover* (high altitude, terminal dive) missile launched at a range of 135 nautical miles on a relative bearing of 060°. This missile is designated *Threat A*.
- ▶ *Sunstroke* (10 meter sea skimmer) missile launched at a range of 40 nautical miles on a relative bearing of 120°. This missile is designated *Threat B*.

The launching platforms are two different air contacts which displayed no hostile intent prior to missile launch. Figure 4-3 depicts the scenario graphically along with missile flight profiles.

Using the formulations presented in the analysis section and the timeline Table 4-3, the following results are given:

a. *Threat A* encounter:

- (1) Missile engagement (9 missiles - 6 SM-1/2, 3 RAM) -

by using (4-6) with $n = 9$ missiles and $p = 0.7$ (a typical value for defensive missile system against incoming missile threat):

$$\begin{aligned} P_{kill}(A) &= 1 - (1 - 0.7)^9 \\ &= 0.999980 \end{aligned} \tag{4-10}$$

- (2) Mk 15 Phalanx CIWS engagement -

one 6.5 second burst that covers the entire effective range of the Phalanx yields, using Table 4-2, a kill probability of:

$$P_{kill} = 0.85$$

- (3) Mk 45 5"/54 Medium Caliber gun encounter - not used.

- (4) Jamming and Decoy $P_{kill}(C)$ is given as 0.4 by (4-8).

The overall kill probability of *Threat A* is found by using (4-3) and the values found in (1) through (4) above:

$$P_{kill,Threat A} = 1 - [1 - 0.999980][1 - 0.85][1 - 0.4] \quad (4-11)$$

$$= .9999982$$

Note the running cumulative probabilities in the right hand column of the *Threat A* encounter time line. The final value of 0.999997 does not include the Jamming and Decoy kill probability.

b. *Threat B* encounter:

- (1) Missile engagement (6 missiles - 2 SM-1/2, 4 RAM) -
using (4-6) with $n = 6$ missiles and $p = 0.7$:

$$P_{kill}(A) = 1 - (1 - 0.7)^6 \quad (4-12)$$

$$= 0.99927$$

- (2) Mk 15 Phalanx CIWS engagement -
one 6.5 second burst that covers the entire effective range of the Phalanx yields, using Table 4-2, a kill probability of:

$$P_{kill} = 0.5$$

- (3) Mk 45 5"/54 Medium Caliber gun encounter - not used.
(4) Jamming and Decoy $P_{kill}(C)$ is given as 0.4 by (4-8).

The overall kill probability of *Threat B* is found by using (4-3) and the values found in (1) through (4) above:

$$P_{kill,Threat B} = 1 - [1 - 0.99927][1 - 0.5][1 - 0.4] \quad (4-13)$$

$$= 0.999978$$

Note the running cumulative probabilities in the right hand column of the *Threat B* encounter time line. The final value of 0.99964 does not include the Jamming and Decoy kill probability.

The probability that the ship will take a hit during this scenario is found using (4-4):

$$\begin{aligned} P(\text{hit}) &= 1 - [P_{\text{kill, Threat A}} \cdot P_{\text{kill, Threat B}}] \\ &= 1 - (0.9999982)(0.999978) \\ &= 23.8 \times 10^{-6} \end{aligned} \quad (4-14)$$

The expected number of hits is found using (4-5):

$$\begin{aligned} HT_{\text{exp}} &= P(\text{hit}) \cdot m \\ &= (23.8 \times 10^{-6}) \cdot 2 \\ &= 47.6 \times 10^{-6} \end{aligned} \quad (4-15)$$

c. Summary

To achieve a 99.9% kill probability of each threat indicates that the minimum combat system required is:

- (1) 6 SM-2(ER)
- (2) 2 SM-1(ER)
- (3) 2 independent illuminators
- (4) 4 RAM
- (5) 1 CIWS mount
- (6) ECM system

Additional requirements include a long range air search radar, a surface search radar, a missile FCS, and an integrated combat system.

3. SCENARIO II: Simultaneous launched sea skimming missiles

This scenario involves simultaneous launch of three threat missiles:

- ▶ *Sunstroke* (10 meter sea skimmer) missile launched at a range of 65 nautical miles on a relative bearing of 090°. This missile is designated *Threat A*.
- ▶ *Seagull* (15 meter sea skimmer) missile launched at a range of 15 nautical miles on a relative bearing of 210°. This missile is designated *Threat B*.
- ▶ *Sunstroke* (10 meter sea skimmer) missile launched at a range of 50 nautical miles on a relative bearing of 330°. This missile is designated *Threat C*.

The launching platforms are three different surface contacts which displayed no hostile intent prior to missile launch. Figure 4-4 depicts the scenario graphically along with missile flight profiles. Using the formulations presented in the analysis section and the timeline Table 4-5, the following results are given:

a. *Threat A* encounter:

- (1) Missile engagement (6 missiles - 2 SM-1/2, 4 RAM) -

using (4-6) with $n = 6$ missiles and $p = 0.7$ (a typical value for defensive missile system against incoming missile threat):

$$\begin{aligned} P_{kill}(A) &= 1 - (1 - 0.7)^6 \\ &= 0.99927 \end{aligned} \tag{4-16}$$

- (2) Mk 15 Phalanx CIWS engagement -

one 4.0 second burst that covers the entire effective range of the Phalanx yields, using Table 4-2, a kill probability of:

$$P_{kill} = 0.5$$

(3) Mk 45 5"/54 Medium Caliber gun encounter -

three rounds at ranges indicated on the time line giving a kill probability using (4-8) of:

$$P_{kill} = 0.52$$

(4) Jamming and Decoy $P_{kill}(C)$ is given as 0.4 by (4-8).

The overall kill probability of *Threat A* is found by using (4-3) and the values found in (1) through (4) above:

$$\begin{aligned} P_{kill, Threat A} &= 1 - [1 - 0.99927][1 - 0.5][1 - 0.52][1 - 0.4] \\ &= 0.99989 \end{aligned} \quad (4-17)$$

Note the running cumulative probabilities in the right hand column of the *Threat A* encounter time line. The final value of 0.9998 does not include the Jamming and Decoy kill probability.

b. *Threat B* encounter:

(1) Missile engagement (12 missiles - 4 SM-1/2, 8 RAM) -
using (4-6) with $n = 12$ missiles and $p = 0.7$:

$$\begin{aligned} P_{kill}(A) &= 1 - (1 - 0.7)^{12} \\ &= 0.9999995 \end{aligned} \quad (4-18)$$

(2) Mk 15 Phalanx CIWS engagement -

one 6.5 second burst that covers the entire effective range of the Phalanx yields , using Table 4-2, a kill probability of:

$$P_{kill} = 0.7$$

(3) Mk 45 5"/54 Medium Caliber gun encounter -

38 rounds, with approximately one round fired every 3 seconds starting at a range of 13.8 nm as indicated on the time line. The kill probability using (4-8) is:

$$P_{kill} = 0.934$$

(4) Jamming and Decoy $P_{kill}(C)$ is given as 0.4 by (4-8).

The overall kill probability of *Threat B* is found by using (4-3) and the values found in (1) through (4) above:

$$\begin{aligned} P_{kill, ThreatB} &= 1 - [1 - 0.9999995][1 - 0.7][1 - 0.934][1 - 0.4] \\ &= 0.999999993 \end{aligned} \quad (4-19)$$

Note the running cumulative probabilities in the right hand column of the *Threat B* encounter time line. The final value of 0.99999988 does not include the Jamming and Decoy kill probability.

c. *Threat C* encounter:

- (1) Missile engagement (5 missiles - 1 SM-1/2, 4 RAM) -
using (4-6) with $n = 5$ missiles and $p = 0.7$:

$$\begin{aligned} P_{kill}(A) &= 1 - (1 - 0.7)^5 \\ &= 0.9976 \end{aligned} \quad (4-20)$$

- (2) Mk 15 Phalanx CIWS engagement -
one 6.5 second burst that covers the entire effective range of the
Phalanx yields , using Table 4-2, a kill probability of:

$$P_{kill} = 0.5$$

- (3) Mk 45 5"/54 Medium Caliber gun encounter - not used.
(4) Jamming and Decoy $P_{kill}(C)$ is given as 0.4 by (4-8).

The overall kill probability of *Threat C* is found by using (4-3) and the values found in (1) through (4) above:

$$\begin{aligned} P_{kill, ThreatC} &= 1 - [1 - 0.9976][1 - 0.5][1 - 0.4] \\ &= 0.99927 \end{aligned} \quad (4-21)$$

Note the running cumulative probabilities in the right hand column of the *Threat C* encounter time line. The final value of 0.9988 does not include the Jamming and Decoy kill probability.

The probability that the ship will take a hit during this scenario is found using (4-4):

$$\begin{aligned} P(\text{hit}) &= 1 - [P_{\text{kill, Threat A}} \cdot P_{\text{kill, Threat B}} \cdot P_{\text{kill, Threat C}}] \\ &= 1 - (0.99989)(0.999999993)(0.99927) \\ &= 840 \times 10^{-6} \end{aligned} \quad (4-22)$$

The expected number of hits is found using (4-5):

$$\begin{aligned} HT_{\text{exp}} &= P(\text{hit}) \cdot m \\ &= (840 \times 10^{-6}) \cdot 3 \\ &= 2.52 \times 10^{-3} \end{aligned} \quad (4-23)$$

d. Summary

To achieve a 99.9% kill probability of each threat indicates that the minimum combat system required is:

- (1) 7 SM-1(ER)
- (2) 2 independent illuminators
- (3) 10 RAM
- (4) 2 CIWS mount
- (5) 1 5"/54 gun mount
- (6) ECM system

Additional requirements include a long range air search radar, a surface search radar, a missile FCS, and an integrated combat system.

4. SCENARIO III: Two simultaneous launched mobile sea skimming missiles and a delay launched sea skimming missile

This scenario involves simultaneous launch of three threat missiles:

- ▶ *Seagull* (15 meter sea skimmer) missile launched at a range of 15 nautical miles on a relative bearing of 030° at time $t = 0s$. This missile is designated *Threat A*.
- ▶ *Seagull* (15 meter sea skimmer) missile launched at a range of 10 nautical miles on a relative bearing of 150° at time $t = 0s$. This missile is designated *Threat B*.
- ▶ *Sunstroke* (10 meter sea skimmer) missile launched at a range of 20 nautical miles on a relative bearing of 320° at time $t = 10s$. This missile is designated *Threat C*.

The *Seagull* launching platforms are two different surface contacts (fishing craft) which displayed no hostile intent prior to missile launch. These fishing craft were hidden amongst other fishing craft, making them impossible to distinguish. The *Sunstroke* missile is launched ten seconds after the two *Seagull* missiles from a surface contact which was being closely monitored. Figure 4-5 depicts the scenario graphically along with missile flight profiles.

Using the formulations presented in the analysis section and the timeline Table 4-6, the following results are given:

a. *Threat A* encounter:

- (1) Missile engagement (12 missiles - 4 SM-1, 8 RAM) -
using (4-6) with $n = 12$ missiles and $p = 0.7$:

$$\begin{aligned} P_{kill}(A) &= 1 - (1 - 0.7)^{12} \\ &= 0.99999946 \end{aligned} \tag{4-24}$$

- (2) Mk 15 Phalanx CIWS engagement -

one 6.5 second burst that covers the entire effective range of the Phalanx yields , using Table 4-2, a kill probability of:

$$P_{kill} = 0.7$$

(3) Mk 45 5"/54 Medium Caliber gun encounter - not used.

(4) Jamming and Decoy $P_{kill}(C)$ is given as 0.4 by (4-8).

The overall kill probability of *Threat A* is found by using (4-3) and the values found in (1) through (4) above:

$$\begin{aligned} P_{kill, Threat A} &= 1 - [1 - 0.99999946][1 - 0.7][1 - 0.4] \\ &= 0.99999990 \end{aligned} \quad (4-25)$$

Note the running cumulative probabilities in the right hand column of the *Threat A* encounter time line. The final value of 0.999999841 does not include the Jamming and Decoy kill probability.

b. *Threat B* encounter:

(1) Missile engagement (10 missiles - 2 SM-1, 8 RAM) -
using (4-6) with $n = 10$ missiles and $p = 0.7$:

$$\begin{aligned} P_{kill}(A) &= 1 - (1 - 0.7)^{10} \\ &= 0.999994 \end{aligned} \quad (4-26)$$

(2) Mk 15 Phalanx CIWS engagement -

one 6.5 second burst that covers the entire effective range of the Phalanx yields , using Table 4-2, a kill probability of:

$$P_{kill} = 0.7$$

(3) Mk 45 5"/54 Medium Caliber gun encounter -

7 rounds, with approximately one round fired every 3 seconds starting at a range of 2.5 nm as indicated on the time line. The kill probability using (4-8) is:

$$P_{kill} = 0.8749$$

- (4) Jamming and Decoy $P_{kill}(C)$ is given as 0.4 by (4-8).

The overall kill probability of *Threat B* is found by using (4-3) and the values found in (1) through (4) above:

$$\begin{aligned} P_{kill,ThreatB} &= 1 - [1 - 0.999994][1 - 0.7][1 - 0.8749[1 - 0.4]] \\ &= 0.9999999 \end{aligned} \quad (4-27)$$

Note the running cumulative probabilities in the right hand column of the *Threat B* encounter time line. The final value of 0.9999998 does not include the Jamming and Decoy kill probability.

c. Threat C encounter:

- (1) Missile engagement (4 RAM) -

using (4-6) with $n = 4$ missiles and $p = 0.7$:

$$\begin{aligned} P_{kill}(A) &= 1 - (1 - 0.7)^4 \\ &= 0.9919 \end{aligned} \quad (4-28)$$

- (2) Mk 15 Phalanx CIWS engagement -

one 6.5 second burst that covers the entire effective range of the Phalanx yields , using Table 4-2, a kill probability of:

$$P_{kill} = 0.5$$

- (3) Mk 45 5"/54 Medium Caliber gun encounter - not used.

- (4) Jamming and Decoy $P_{kill}(C)$ is given as 0.4 by (4-8).

The overall kill probability of *Threat C* is found by using (4-3) and the values found in (1) through (4) above:

$$\begin{aligned} P_{kill,ThreatC} &= 1 - [1 - 0.9919][1 - 0.5][1 - 0.4] \\ &= 0.9976 \end{aligned} \quad (4-29)$$

Note the running cumulative probabilities in the right hand column of the *Threat B* encounter time line. The final value of 0.99595 does not include the Jamming and Decoy kill probability.

The probability that the ship will take during this scenario is found using (4-4):

$$\begin{aligned} P(\text{hit}) &= 1 - [P_{\text{kill, Threat A}} \cap P_{\text{kill, Threat B}} \cap P_{\text{kill, Threat C}}] \\ &= 1 - (0.99999999)(0.9999999)(0.9976) \\ &= 2.4 \times 10^{-3} \end{aligned} \quad (4-30)$$

The expected number of hits is found using (4-5):

$$\begin{aligned} HT_{\text{exp}} &= P(\text{hit}) \cdot m \\ &= (2.4 \times 10^{-3}) \cdot 3 \\ &= 7.2 \times 10^{-3} \end{aligned} \quad (4-31)$$

d. Summary

A 99.9% kill probability of each threat is not possible due to *Threat C* kill probability of only 99.76%. To achieve 99.9% kill probability on *Threat A* and *Threat B*, and a 99.76 kill probability on *Threat C* indicates that the minimum combat system required is:

- (1) 6 SM-1(ER)
- (2) 2 independent illuminators
- (3) 11 RAM
- (4) 1 CIWS mount
- (5) ECM system

Additional requirements include a long range air search radar, a surface search radar, a missile FCS, and an integrated combat system.

Figure 4-5. Scenario III.

5. SCENARIO IV: Simultaneous launch of shoulder missiles

This scenario involves simultaneous launch of two shoulder fired threat missiles:

- ▶ *Stinger* (shoulder mounted, IR home) missile launched at a range of 1.5 nautical miles on a relative bearing of 300°. This missile is designated *Threat A*.
- ▶ *Stinger* (shoulder mounted, IR home) missile launched at a range of 2.0 nautical miles on a relative bearing of 130°. This missile is designated *Threat B*.

The *Stinger* launches occur simultaneously from two different pleasure craft which displayed no hostile intent prior to missile launch. Figure 4-6 depicts the scenario graphically along with missile flight profiles.

Using the formulations presented in the analysis section and the timeline Table 4-6, the following results are given:

a. *Threat A* encounter:

(1) Missile engagement - none

(2) Mk 15 Phalanx CIWS engagement -

one 3.5 second burst that covers the entire effective range of the Phalanx. A kill probability for the *Stinger* is estimated to be about 0.3 due to the small size of the missile and short reaction time:

$$P_{kill} = 0.3 \quad .$$

(3) Mk 45 5"/54 Medium Caliber gun encounter - not used.

(4) Jamming and Decoy $P_{kill}(C)$ is considered ineffective for this scenario.

The overall kill probability of *Threat A* is found by using (4-3) and the values found in (1) through (4) above:

$$\begin{aligned} P_{kill, Threat A} &= 1 - [1 - 0.3] \\ &= 0.3 \quad . \end{aligned} \tag{4-11}$$

b. Threat B encounter:

(1) Missile engagement - not used.

(2) Mk 15 Phalanx CIWS engagement -

one 5.0 second burst that covers the entire effective range of the Phalanx. A kill probability for the *Stinger* is estimated to be about 0.4 due to the small size of the missile, but there is slightly longer reaction time as compared to Paragraph IV.B.5.a above:

$$P_{kill} = 0.4$$

(3) Mk 45 5"/54 Medium Caliber gun encounter - not used.

(4) Jamming and Decoy $P_{kill}(C)$ is considered ineffective for this scenario.

The overall kill probability of *Threat B* is found by using (4-3) and the values found in (1) through (4) above:

$$\begin{aligned} P_{kill, threat B} &= 1 - [1 - 0.4] \\ &= 0.4 \end{aligned} \quad (4-13)$$

The probability that the ship will take a hit during this scenario is found using (4-4):

$$\begin{aligned} P(\text{hit}) &= 1 - [P_{kill, Threat A} \cdot P_{kill, Threat B}] \\ &= 1 - (0.3)(0.4) \\ &= 0.88 \end{aligned} \quad (4-14)$$

The expected number of hits is found using (4-5):

$$\begin{aligned} HT_{exp} &= P(\text{hit}) \cdot m \\ &= (0.88) \cdot 2 \\ &= 1.76 \end{aligned} \quad (4-15)$$

c. Summary

The minimum combat system required is:

(1) 2 CIWS mount

Additional requirements include a surface search radar and an integrated combat system.

6. SUMMARY:

Based on the four outlined scenarios, the following minimum number of systems and items will be incorporated into the initial design of the RDS-2010:

a. A combat system consisting of the following engagement elements will be used:

- 24 cell VLS (VLS loadout as required by mission)**
- 2 RALS (Ram Alternate Launcher System)**
- 2 MK 15 PHALANX**
- 1 5"/54 MK 45 GUN MOUNT w/ FCS**
- 2 SPG-XX ILLUMINATORS**
- 1 SLQ-32(V3) w/ 2 DECOY LAUNCHERS**
- 1 LONG RANGE AIR SEARCH RADAR**
- 1 SURFACE SEARCH RADAR**

b. The ship must be able to sustain a hit from a STINGER size missile and maintain mission capabilities.

c. Although the scenarios, as presented, would imply no requirement for the SAR-8 IR sensing system, the weakest defensive capability lies in the short range, hand-launched missile system (STINGER types). Research needs to be accomplished in the area of quick-reaction detection of a missile launch and autonomous defeat of the weapon. This is envisioned as some type of automatic flare system coupled to a sensor like the SAR-8. Immediately on detection of missile launch, a flare-type decoy would be deployed to draw the missile away from the ship. This flare will have to be propelled along a predetermined flight path to allow the missile to lock-in on it and then be drawn away from the ship. Another area in which research is required is active IR emissions for disabling the missile seeker, by overload or deception.

C. COMBAT SYSTEM DESCRIPTION AND ARCHITECTURE

1. Design Statement

The RDS-2010 Combat System and supporting elements are designed to meet the requirements delineated in Section II.B. Specifically, the combat system must:

- a. provide AAW self-defense against limited intensity/direction threats;
- b. provide ASUW against third-world surface naval forces;
- c. provide ASW in deep and shallow water while employed independently;
- d. support amphibious assaults;
- e. attack high value land based military targets;
- f. receive real time targeting information from diverse sources; and
- g. operate in mine infested waters.

These requirements and the evaluation of threat scenarios (Section IV.B) confirmed and refined the combat system element selection (Section III.C.4).

2. Top Level Design Goals

Based on the above requirements, the top level combat system design goals are:

- a. self-defense;
- b. discriminate targets to minimize unwanted damage;
- c. fight hurt--minimize damage by effective assessment and rapid restoration;
- d. continuous high readiness for extended periods;
- e. self-sufficient-capable of independent or small group operations;
- f. improved anti-terrorist security;
- g. improved counter targeting through decoys and deception devices;
- h. built in automatic reconfigurability of ship's systems based on evolving threat scenario/condition;
- i. built in fault identification with rapid repair capability; and
- j. combat system automation with preset options for layered self-defense.

3. Combat System Description and Capability

Figure 4-7 depicts the functional arrangement of the RDS-2010 combat system, including major data flow connectivity. General design attributes include:

a. Primary connectivity between elements is provided by a multi-channel, multi-redundant fiber optic ring bus. Envisioned is a minimum of five functionally redundant data buses geographically separated within the ship to decrease vulnerability. Each system has multiple channel capacity and each channel has the capability to carry multiplexed data. Determination of data types and flow that allow use of multiplexing vice dedicated channels must be determined during detailed combat system design. As a minimum, each ship enclave contains one *bus manager* to ensure surviving enclaves have data bus capability. The application of the Fiber Optic Data Multiplexing System (FODMS) and Fiber Optic Interior Voice Communications System (FOIVCS) improves capability and enhances survivability while reducing ship acquisition cost, primarily via the associated weight and volume savings.

b. Two manned Command and Decision (C&D) elements (i.e., Combat Information Center - CIC) are provided, one acting as the ship's primary CIC (CIC #1) and the other an alternate CIC (CIC #2). Functional redundancy is provided between these two C&D elements, though actual hardware, layout, and number of operator stations is scaled down in CIC #2. The two CICs are located in separate enclaves. The C&D element utilized the available sensors and external information data stream to provide the necessary information to create a complete tactical picture. The computer processing power required by all modules of the C&D element is distributed amongst the modules providing redundant capacity and eliminating processing bottlenecks. There will be no "central computer" in the traditional sense. The tactical picture created must be complete and coherent enough to provide necessary reaction time for ship defense. The major modules of the C&D element are:

(1) *Detect and Track.* This module determines contact detection and develops track files on contact data received from various ship's sensors. The module exports the track files to the correlate module and ring bus for use by the other C&D correlate module.

(2) *Correlate.* This module develops correlation of data from various detection elements on and off the ship and Detect & Track module to develop a central track file. This provides precise localization and identification of all contacts. The central track file is exported to the C&D control element and ring bus for use by the other C&D element's C&D module.

(3) *Command and Decision Module.* This performs assessment of detection tracks as friendly, neutral, or enemy. It makes engagement decisions and sets the engagement priorities. Additionally, it coordinates own ship operations with the operations of other ships or aircraft in the task force. The decision to engage or not is made in this module. Capable of fully automated ship self-defense operation, the level of automation employed is determined by the responsible person in charge.

(4) *Multipurpose Consoles.* These represent generic, programmable operator interface consoles that provide the man/machine interface with all modules of the C&D element. These consoles are militarized versions of modern, commercial workstations. Additionally, there is a large screen multifunctional display for large area geographic display of tactical situations.

(5) *Weapons Control Module.* The actual weapons selection and engagement coordination is performed by this module. It also maintains an inventory of available ordnance and carries out engagement planning needed for each weapons release. The module coordinates the use of individual weapon elements to prevent interference between own ship weapons and damage to friendly forces. Finally, the module provides the kill assessment for each individual engagement.

c. The *power interface module* provides the interface management function between the ship's engineering plant electric plant control module and the combat system with regards to load shed command and coordination. On loss of electrical generation capacity due to casualty, the electric plant control module sends a load shed command to the combat system, essentially conveying available generating capacity and bus configuration. The interface module communicates with the C&D element to determine combat system needs commensurate with tactical situation. With a balance between power requirements (demand) versus generating capacity, the power system interface module transmits shut down^o commands to appropriate combat system elements and also communicates electric plant reconfiguration requests to the electric plant control module.

d. *Readiness assessment, fault detection and localization.* The survivability management and readiness assessment (SM/RA) module works in conjunction with the various combat system element's built-in test and evaluation (BITE) capabilities to provide an integrated system readiness assessment. All the combat system elements must have this BITE capability. The survivability management sub-module uses the system status (readiness assessment) and tactical situation (C&D element) to direct combat system reconfiguration to employ alternate functionality during casualty situations. An additional BITE feature is the requirement that all combat system elements provide automated troubleshooting capability. This enhances fault localization and subsequent repair to place equipment fully operational in as short a time as practical. The readiness assessment sub-module provides the commanding officer and tactical action officer with a real-time comprehensive assessment of the ship's ability to continue fighting. Additionally, it enables the combat system officer of the watch and engineering officer of the watch to better coordinate efforts to maintain/recover mission readiness prioritized to current mission

^o a shut down command will cause a device specific action ranging from total device shutdown to placing the device in a power savings (standby) mode

needs. The readiness data includes current status of mission capabilities, times to failure and times to recovery. Readiness data is obtained from all systems including auxiliaries that supply the individual combat systems.

e. *Survivability and reconfigurability.* System survivability is enhanced by a number of design features, including:

- (1) dual C&D element functionality which is geographically separated in CIC #1 and CIC #2;
- (2) alternate sensor capability in all spectrums except IR detection;
- (3) multiple, redundant connectivity between combat system elements;
- (4) graceful degradation of overall system capability upon partial power loss through smart load shed management.

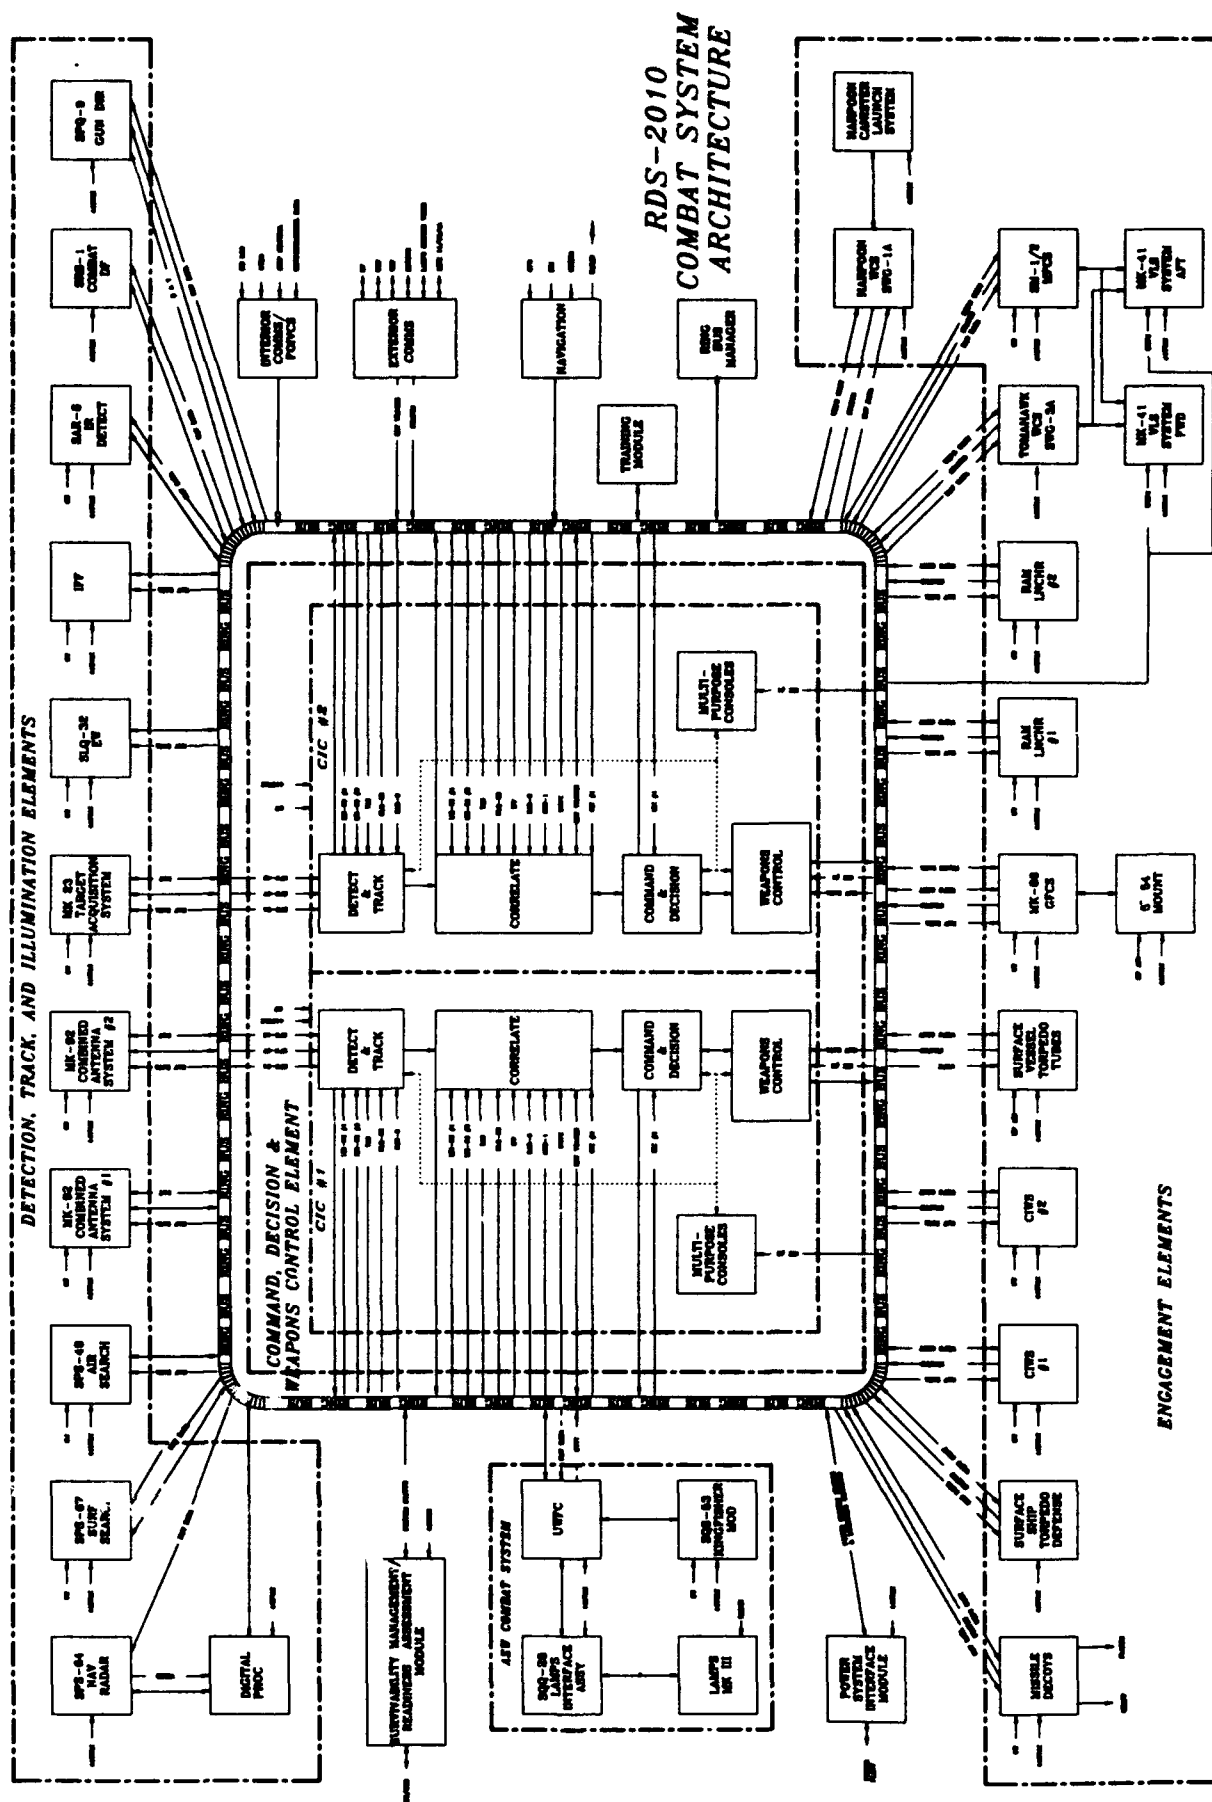

With the available redundant/alternate functional capabilities, system reconfiguration is practical to optimize combat system employment during casualty conditions. This feature is addressed in Section IV.C.3.d above.

f. *Embedded training.* The integrated combat system includes an embedded training module to allow realistic threat scenario engagement exercises. These training scenarios will exercise the C&D element and watchstanders. Essentially, this entails the capability to run pre-programmed engagement scenarios by injection of track and other necessary data directly onto the data bus.

g. *Embedded support service management.* Primary support services for the combat system are electrical, chilled water, sea water, ambient space cooling and dehumidification, and high pressure air. With the enclaving scheme, each enclave has fully self-contained capability with the exception of electrical power generation. Electrical power generation is limited to the three enclaves containing the two engine rooms and one auxiliary machinery space aft. Status of these systems is maintained by Damage Control Central (DCC)/Central Control Station (CCS) and the engineering plant status module.

Support service configuration is coordinated with required combat system capability as determined by the tactical situation during casualty situations. Maximum capability will be maintained consistent with available capacity remaining during casualties. With input to/from the survivability management system, certain automatic damage control actions can be accomplished before a weapons hit occurs. For instance, upon detection of appropriate heat and smoke levels following a detonation within a compartment, the pertinent fire sprinklers can be started to douse the fire and cool adjacent compartment's bulkheads and ventilation dampers can be automatically closed. Also, the electric plant can be shifted before fire removes distribution capability that is routed through the scene of the fire.

h. *Automated Communications Suite.* To provide manning reduction and increase external communication throughput, the external communications suite is automated. This automation allows incorporation of the external communications function as an integral part of the integrated combat systems suite. Features such as automated electronic message routing with dispersed remote terminals streamline message dissemination. Automated external connectivity allows integration of this ship in a task force/battle group scenario. Export of sensor data and import of weapons command functions extends the integrated fighting power of the task force/battle group. Import of real time data from outer sources provides a coherent, integrated picture of the battle space. With continuously updated information the ship could support or be supported by other ships, shooting targets its own sensors cannot detect.

D. BATTLE ORGANIZATION AND BATTLE STATION LOCATIONS

The manning requirements for the ship drive many design parameters, especially in the H, M & E areas. Manning is primarily driven by watchstation requirements during battle conditions, and driven to a lesser extent by normal ship operations. For this reason, the Battle Organization and Battle Station Locations, along with the envisioned manning plan for the RDS-2010 are included in this chapter.

The RDS 2010's Condition I and Condition III Battle Organizations are given in Figures 4-8 and 4-9, respectively. The connectivity of the watch organization is for supervisory functions only, and has nothing to do with the flow of information to each watch station. Since each watch station will be connected to the data multiplexed ring bus, all watch stations will have access to any desired information. The watch stations that require consoles will be established with either one of three different types;

1. a multi-purpose console capable of performing any watch station function,
2. an Aegis-type large screen multi-purpose Command and Display console,
3. or a watch station specific console used only for local equipment control and specific functions.

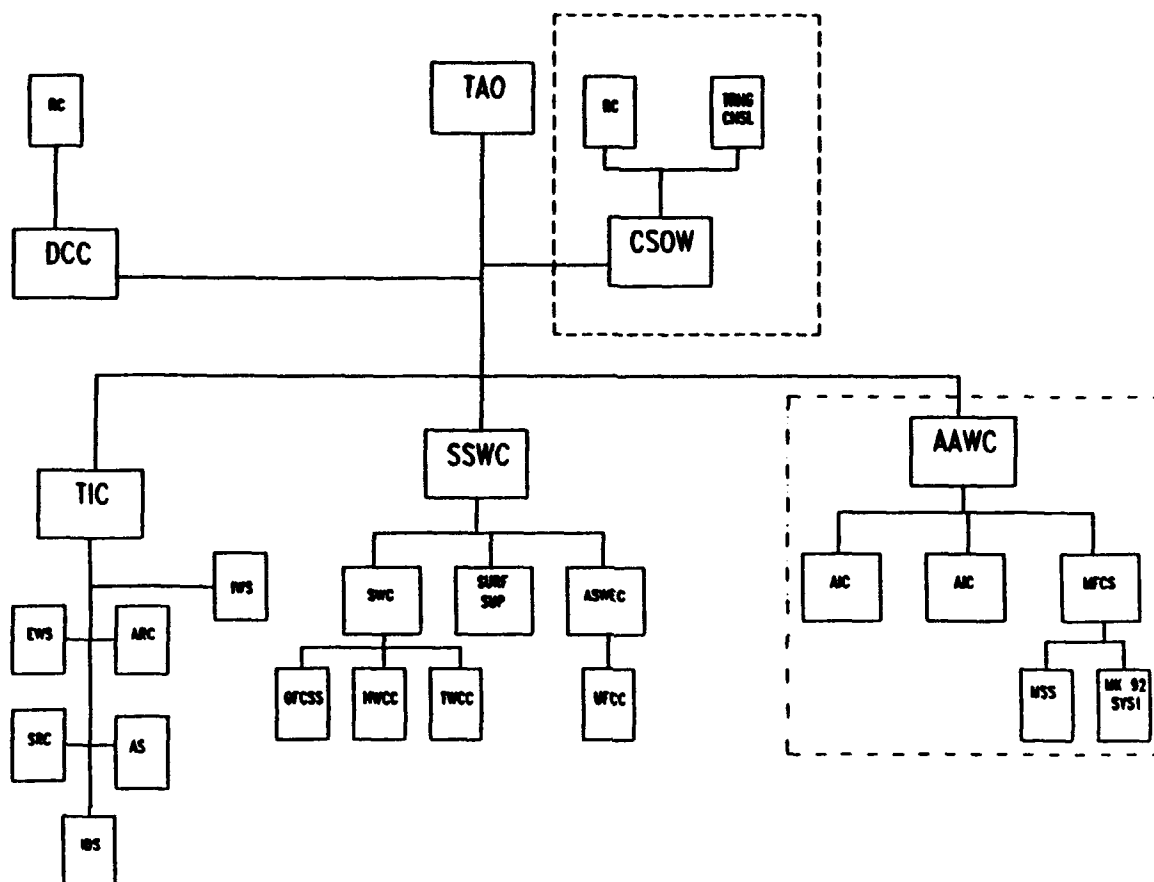

The desired capability of the combat system watch team during Condition III is that it can fight the ship in a short duration, limited capacity until the ship can man Condition I watch stations. The RDS 2010's manning will allow, with minor exceptions, all watch stations to be stood in a three section, 4 hours on/8 hours off, watch rotation. This will allow ample time for the off watch sections to conduct training, maintenance and housekeeping. The envisioned manning and departmental organization of the RDS 2010 is shown in Table 4-7 and Figure 4-10, respectively. It is understood that this is not a formal manning document, but an attempt by the team to determine the number of personnel required to man the ship. Additionally, it is useful for analyzing whether this number supports the reduced manning goal.

V. HULL, MECHANICAL, AND ELECTRICAL FEASIBILITY STUDIES

Once the ship's major payload, *the combat system*, is determined in terms of specific elements and their quantities, then the element's size, weight, power and service requirements can be used as a starting point for determining the ship's hull, mechanical, and electrical characteristics required to support the payload. This next phase of the feasibility studies uses a computer based ship design tool, supplied by NAVSEA, known as the Advanced Surface Ship Evaluation Tool (ASSET). Within ASSET there exists a series of computational modules which address a specific domain of ship design, such as hull geometry, hull structure, resistance, propulsion, machinery, weight, space, hydrostatics, seakeeping, manning, or cost. Through a unique command language, the user directs the execution of the modules. In using the input support module, essentially all ship characteristics which are known *a priori* (i.e., such as the above mentioned payload characteristics and the defined ship performance characteristics) are entered into and stored in this ASSET program's data bank. The designer then, through various commands, directs the program to iteratively calculate the major ship's characteristics until the data converges on a solution. The modules of the ASSET program have been designed in such a way as to provide the capability of design synthesis and analysis. The converged solution, however, may or may not meet all the desired characteristics. It is at this point that the ship design team must begin tradeoff decisions in an attempt to gain a balanced ship with as many of the desired characteristics that are economically and technically feasible.

A. INITIAL CONVERGENCE

Table 5-1 summarizes the major ship's characteristics attained during the first convergence of the ship RDS 2010 using the Monohull Surface Combatant version of the ASSET program. Since the design has not been optimized, the complete and voluminous output reports of ASSET are not included with this report. The primary goal at this stage of the feasibility studies was to gain enough experience and confidence with the ASSET program to obtain a converged design. The next stage of feasibility studies will be to iterate, using ASSET, and attempt to optimize the design using the top level design goals and performance characteristics for guidance. This process will entail making design decisions, attempting to balance numerous competing design goals until a ship is obtained which reasonably meets the set design requirements and constraints. The ability to meet all design goals simultaneously is in no way guaranteed.

Portions of this feasibility study use alternative elements to those selected in earlier phases of the design. This was necessary because of the inability of this computer program to successfully accommodate electric drive with electric power generation. When the design team attempted to use the electric propulsion generators, each main machinery room was required to be 114 feet in length. This is another area requiring modification in future versions of the ASSET series of programs.

In general the size of the ship is too large for the present payload. Some of the excess volume and length is due to the use of the double hull which this ASSET program currently does not incorporate. It also appears that the ASSET program is heating and ventilating the volume in the double hull. A decision was made to use the portion of the double hull volume below the water line for tankage, so this also needs to be adjusted.

B. FINALIZATION OF MAJOR SHIP CHARACTERISTICS AND COMBAT SYSTEMS ELEMENTS

The previous section addressed work accomplished during the first academic quarter, when the RDS 2010 was modeled computationally and the synthesis portion of ASSET used in order to ensure convergence. However, at that time the cost did not come within the limit of \$350 million. The first order of business in the second academic quarter was to lower the cost. To make the design economically feasible and acceptable, many factors were adjusted to bring the cost within a workable range. Table 5-2 summarizes the major ship's characteristics attained during the final convergence of the ship RDS 2010 using the Monohull Surface Combatant version of the ASSET program.

The cost was significantly reduced through various adjustments of hull material, stiffener spacing, deckhouse structure, and principal dimensions. The hull and structural material was changed to steel with a higher strength-to-weight ratio, HY-80, resulting in a significant savings weight (200 tons). This in turn reduced the powering requirement, shrinking the length and displacement further because of the decrease in fuel required for endurance. Although this provided a significant cost savings as predicted by the ASSET cost module, it is surmised that the cost reduction in the real world might not have been as grand because of the added labor and quality assurance procedures associated with welding HY-80 steel.

Stiffener spacing was adjusted from a maximum allowed spacing of 24 inches to 48 inches, permitting the Hull Structures module of ASSET to better optimize the sizing and placement of stiffeners considering the complex relationship between the stiffeners and the plating to which they are welded. The use of enclaved auxiliary systems and fiber optic cabling will minimize the amount of space needed in the overhead. The hull average deck height was lowered from 10.5 feet to 9.95 feet to minimize the internal volume of the ship and permit the addition of another deck. The prismatic coefficient was adjusted in order to attempt a positive reduction in the size of the hull, but there was no apparent cost or volume savings. Apparently, the initial value of $C_p = 0.65$ was near optimum. The maximum section coefficient was adjusted downward as far as possible within the constraints of the hydrostatic limitations. This brought about savings in fuel usage and a higher sustained speed as a result of lowered resistance.

At the time of initial convergence the deckhouse size indicator had been set at "max", causing the deckhouse to extend over 50% of the ship at a three deck height. This was changed to "min" so that only the volume and area required for equipment and personnel would be generated, reducing the deckhouse weight by about 400 tons. Additionally, the

hull flare angle and the deckhouse side angle offset were changed from zero to seven degrees in order to reduce the effective radar cross-section and improve appearance. We removed the forward auxiliary machinery room after assessing the machinery requirements recommended by the initial convergence. Removal of this space which was nearly empty returned approximately 10,000 ft³ of internal arrangeable volume.

The double hull posed some challenges because the ASSET program is unable to deal directly with this concept. In order to have a double hull volume which is not lighted, heated nor air conditioned, it was necessary to make data base adjustments in the endurance range and payload to account for the extra volume available for tankage. By not lighting, heating nor air conditioning the double hull void, a significant reduction in electrical power was realized. The double hull volume below the waterline is used for endurance fuel tankage, while the volume above the waterline is reserved for buoyancy and for increasing internal blast resistance against anti-ship missile explosions. The issue of whether to fill these spaces with an energy absorbing material or to leave them void must be resolved during subsequent design iterations.

The helicopter hangar area was reduced by half as the helicopter compliment was reduced from two to one for cost reasons. The associated helicopter payload items were also reduced as required to support only one helicopter. The reinforced helicopter deck remains capable of supporting the larger CH-53 Sea King which is used to tow a mine clearing sled and could be used for evacuation of U.S. citizens from political hot spots.

These changes allowed a decrease in bare hull displacement of approximately 2000 tons to the current design displacement which is slightly under 5500 tons. While revisiting the subject of heating, we determined that it would be more cost effective to use a waste heat boiler to carry some of the ship hotel heating requirements. With a smaller ship, the

lighting, heating and ventilation requirements were also reduced, allowing a smaller ship service gas turbine generator set.

The use of integrated electric drive was abandoned during feasibility studies. Designing the RDS 2010 with this developing technology was unacceptable on the basis of the technical risk and cost involved, because the larger machinery rooms needed for the current generation of propulsion generators drove the ship length beyond 500 feet. Instead, the team chose four propulsion gas turbines (two per shaft), driving a standard mechanical reduction gear drive train, as the propulsion plant. Two of the three ship's service generators are powered from power take-off units attached to the reduction gears, one per shaft, to meet power requirements during cruising and battle conditions. The remaining ship's service generator is for standby use and is powered by a dedicated gas turbine. The four main gas turbines, which are currently the smallest available commercially, are larger than required for the ship's propulsion and electrical power needs. Use of even smaller propulsion turbines is preferable, since the mission speed requirements have been exceeded, but they are not presently available in production models. The option of going from the four small gas turbines to two larger gas turbines was not taken because of factors affecting machinery plant survivability and reliability. The fixed pitch propeller had to be replaced with a controllable pitch propeller to remain compatible with this propulsion train. This is a major disadvantage for shallow water operation because of the CRP complexity which makes it less robust than a fixed pitch propeller.

To minimize the technical risk involved in the development of the new mortar system, the first flight is designed to have both the new mortar system and the current version of the vertically launched ASROC.

C. COST REDUCTION SUMMARY

After many major and minor changes, we came to the point of diminishing returns on ship modifications for the sole purpose of cost reduction. The ship cost had been nearly halved from \$850M, yet it did not come within the stringent \$350M requirement. There comes a point in many phases of design at which one phase of design must end before the next phase can begin. This point had arrived since for educational purposes we needed to proceed to the next phase of preliminary design. It was at that time the following request for an adjustment to the cost ceiling was made.

D. REQUEST FOR ADJUSTMENT TO COST CEILING

During the first academic quarter, the RDS 2010 was modeled to be technically feasible, however, the follow-on ship cost did not come within the limit of \$350 million. To make the design economically feasible and acceptable, many factors were adjusted to bring the cost within a workable range. Currently, the projected cost from the ASSET Cost Analysis Module is \$809/476M for the *first/follow-on ships respectively*. The projected cost as determined using the Gibbs and Cox two digit cost estimating scheme was \$290M. To meet the mission requirements and provide adequate self-defense, the cost ceiling per follow-on ship should be raised to \$475M. This is strongly recommended in order to meet the mission requirements without degradation.

Certain features of the vessel could be modified in order to come closer to the present \$350M cost limit. Two likely options are: 1) removal of the LAMPS III system, or 2) reversion to a single hull. The drawback to removal of the LAMPS III system is a major degradation of the ASW mission area. Additionally, a single hull ship would be considerably more vulnerable to missile hits and mine explosions. If capability must be removed to remain within cost constraints, the options are recommended in the given

order because the likelihood of being targeted by a missile is higher than being stalked by a submarine at long range.

In the current political environment it is entirely possible that no new class of ship will ever be built. As shipyards and defense contractors recognize this fact they may consider a reduction in profits in order to keep the production lines operating. This may serve to ameliorate the problem. It is recommended that the cost ceiling be raised to \$475 million dollars for follow-on ships.

E. RESULT OF COST CEILING ADJUSTMENT PROPOSAL

The above proposal was approved and the cost ceiling extended to \$500 million.

VI. THE ENCLAVED SHIP

Ship's survivability is high on the list of design priorities. This is due to the emphasis in the "CNO Tentative Requirement Statement" (Section II.A.3) that this ship be highly survivable *and* minimize crew casualties. The design team considered a major design attribute to enhance the survivability was to enclave the ship. *Enclaving* is a concept for reducing ship vulnerability by dividing the equipment associated with the ship's mission capabilities into subsets which can be located in different autonomous or semiautonomous regions within the ship. This minimizes the loss of mission critical functions caused by a hostile weapon hit and maximizes the ability to fight hurt. Enclaving is the synergistic zoning of the combat system and H, M & E systems into regions which can function independently as required to provide a subset of the ship's mission capability. Without the positive side effects of this synergism, the prospect of *enclaving* could be too costly based on the installation of duplicate system elements. In addition to duplication of functionality, the concept of alternate functionality of equipment is used to enhance the enclaving concept. By this we mean, for instance, the ability to use a surface search radar as a less capable, but backup air search radar. When survivability and cost are approached from the perspective of numbers of ships available to fight, a more survivable ship is a more valuable asset to the nation.

There are two types of decision making involved in designing an enclaved combatant. Major conceptual decision making is usually done by higher authorities while the actual engineering tradeoff decision making is performed by the shipbuilder's detailed design

team. Additionally, since the combat weapon system, H, M & E support systems, propulsion systems and other necessary ship's systems are a complex total ship system package, the need exists for an iterative design approach in which the effects of certain decisions are monitored for overall effect and modified by the total system integrator (ship design management team). The design challenge is to *enclave* while minimizing the addition of duplicate equipment. As the art of interface engineering evolves and standards are narrowed, the ability to *enclave* is enhanced.

The goal is to *enclave* functionality and arrange associated support systems to allow the loss of a single *enclave* without reducing the support services required by the other enclaves to maintain their combat system equipment operational. A worthy goal is to ensure that support systems not included in an *enclave* are available from the adjacent *enclave*. Each *enclave* is provided with self-sufficient damage control capability. Electrical power will be available from the ship's service ring bus and interior communications data will be available from the fiber optic data bus. Although the central damage control console will be located in the Central Control Station, each *enclave* will get its automatic and real time human generated damage control commands via one of the five fiber optic data buses. For the sake of damage control and mission war fighting capability, it is desirable that the personnel be berthed within each *enclave* near their general quarters or damage control station.

For the sake of producibility and reduction in cost, *zones* have been established that often coincide with the *enclave* boundaries. The boundaries extend vertically from the keel to the weather deck and horizontally for two to four subdivisions (i.e. compartments).

A. FACTORS AFFECTING EQUIPMENT COMBINATIONS

There are a number of factors which affect the actual location and the combinational synergism of equipment placement. These factors are the major determinants in the design teams decision making process when it came to locating specific equipment onboard the ship:

1. constraints of topside arrangement;
2. collocation of interdependent or series combat system equipment;
3. separation of functionally parallel combat systems equipment by at least one weapon damage perimeter;
4. *enclave* boundaries determined by existing zones (collective protection, fire, flooding, etc.);
5. balance *enclaving* with other factors of the ship design via the design philosophy;
6. minimize the crossing of boundaries for ease of producibility;
7. armored cable ways protect fiber optic and power cables; and
8. loss of a single enclave will not degrade other enclaves.

B. ENCLAVE ARRANGEMENT

Table 6-1 lists many of the major ship systems and equipment by enclave. Figure 6-1 illustrates the physical enclave boundaries overlaid on the ship.

VII. SHIP'S ELECTRICAL GENERATION AND DISTRIBUTION SYSTEM

The original vision of the ship's electrical generation and distribution system consisted of an integrated electrical drive plant with ship's service power derived from power converters. These power converters would change the unregulated (voltage and frequency) propulsion bus power to 60 Hz, 450 Vac standard shipboard power. This scheme had many merits in an enclaved ship due to the natural distributed ship's service power generation that results. As mentioned in Chapter 5, however, the integrated electric drive option had to be dismissed due to difficulties in manipulating the ASSET program.

We did maintain a form of propulsion derived ship's service power, however. The propulsion plant is a standard two gas turbine per shaft mechanical-reduction gear coupled system. There are power takeoff (PTO) units on each reduction gear coupled to high speed, high frequency generators. The output of these generators feed a solid-state power converter which conditions the power to regulated three-phase, 60 Hz, 450 Vac standard ship's service power. To achieve the required $n-1$ redundant capacity, a third ship's service gas turbine generator (SSGTG) is included in the plant design.

By using PTO fed generators, the need for dedicated prime movers for two of the three ship's service power sources is removed. This should decrease weight and increase available volume within the ship. In addition, high speed generators are smaller and lighter than equivalent power 60 Hz generators.

The distribution scheme chosen is a standard three power source ring bus configuration. Enclaving is enhanced by using a modified zonal distribution scheme off the ring bus with multiple load centers strategically placed throughout the ship. Figure 7-1 shows the ring bus structure. Figure 7-2 shows the geographic locations of the generators

and load centers. Figure 7-3 indicates the interconnectivity of the power distribution system and major ship's loads.

VIII. SHIP DESCRIPTORS

There is some overlap between the end of feasibility studies and the start of preliminary design. In some respects, all work performed after the first successful convergence of an ASSET run could be considered preliminary design. On the other hand, it could be argued that preliminary design began after the major modifications to the initial design concepts were completed and a revised cost ceiling was approved. One obvious departure from actual practice was our use of ASSET beyond the feasibility studies, into what traditionally is considered preliminary design. This adds to the "fog" which surrounds the delineation. Additionally, design aspects such as electrical plant design and combat system definition, which did not use ASSET in any substantial way, make it hard to say which work actions were feasibility studies and which were preliminary design.

At the completion of the design process, however, we have a ship design that would be typical of the work presented at completion of preliminary design. Clearly, the details and rigor of analysis is lacking due to the short time duration and minimal human resources available to complete the work. The previous chapters have shown some of the non-naval architectural design products from preliminary design. This chapter presents the naval architectural "ship descriptors". Some of these items were produced by ASSET whereas other were completed by members of the design team.

One of the many tasks, from the faculty, was to provide the following:

- 1) complete lines drawing, to include sheer, body and waterline plans;
- 2) displacement and other curves;
- 3) curve of static stability;
- 4) general arrangements drawings, showing arrangement for each deck;

- 5) detailed compartment arrangement drawings for:
 - CIC and
 - pilot house;
- 6) discussion of hull damage length chosen (and why);
- 7) floodable length curve illustrating damage length criterion is satisfied;
- 8) structural report consisting of:
 - weight curve,
 - load curve for hull, and
 - midships section design.

A. NAVAL ARCHITECTURAL CURVES

1. Hull Geometry

The ship's lines describe the form of the ship's hull, and are presented in a series of two-dimensional drawings refereed to as the lines drawing. The three basic projections are the sheer plan, the half-breadth plan, and the body plan. Figure 8-1 shows these projection of ships lines for the RDS-2010, without modifications made during preliminary design. These projections were produced manually, using data generated by the ASSET program. Note that ASSET did not include the hull mounted SONAR bow dome.

2. Hull Coefficients

The form coefficients which apply to this ship's hull form were calculated by ASSET and plotted as a function of draft. Figure 8-2 shows the variation of the block coefficient (C_b), prismatic coefficient (C_p) and waterplane area coefficient (C_{wp}) versus draft. Note the design draft was chosen to be 15 feet.

Figure 8-2. Hull Coefficients of Form.

3. Displacement and other curves

The hydrostatic curves, also known as the Curves of Form, were produced by ASSET for the RDS-2010 hull without the bow SONAR dome. These curves are shown in Figure 8-3 and include the following items as designated here:

- A** Displacement in salt water (DISPL) - *(Note: the draft used for this and all the other curves is the mean draft to the bottom of the keel.)*
- B** Moment to trim one inch (MT1)
- C** Tons per inch immersion (TP1)
- D** Transverse metacentric radius (BMT)
- E** Longitudinal metacentric radius (BML)
- F** Center of buoyancy above bottom of keel amidships (KB)
- G** Change in displacement per unit trim by stern (CID1TS)
- H** Wetted surface area (WSURF)
- I** Longitudinal center of buoyancy (LCB)
- J** Longitudinal center of flotation (LCF)

Figure 8-3. Displacement And Other Curves.

4. Static Stability

All ship designs require sufficient initial stability and buoyancy to enable the ship to withstand the effects of external influences and internal movements. *Intact criteria* consists of a number of requirements including withstanding the effect of beam winds, lifting of heavy weights over the side, towline pull, crowding of personnel to one side, high speed turning, and topside icing.

Beam wind, when combined with the ship's roll, is typically the governing case for intact stability. For this ship design, the ship must be expected to weather the full force of tropical cyclones. The criteria for adequate stability under adverse wind and sea conditions is based on a comparison of the ship's righting arm curve and the wind heeling arm curve. Figure 8-4 is the static stability curve and wind heeling arm curve produced by ASSET for the RDS-2010.

Stability is considered satisfactory if (1) the heeling arm at the intersection of the righting arm and heeling arm curves is not greater than 60% of the maximum righting arm; and (2) the area between the two curves to the right of their intersection is not less than 140% of the area between the two curves to the left of their intersection. Inspection of Figure 8-4 shows that both of these criteria are met.

To examine the high speed turn stability problem, the turn heeling arm curve is plotted on the same graph as the static stability curve. This is shown for the RDS-2010 in Figure 8-5. The following criteria must be satisfied to ensure adequate stability: (1) the angle of steady heel does not exceed 10 degrees, (2) the heeling arm at the intersection of the righting arm and heeling arm curves are not more than 60% of the maximum righting arm, and (3) the reserve of dynamic stability (area between the two curves to the right of their intersection) is not less than 40% of the total area under the righting arm curve. Examination of Figure 8-5 shows that all criteria are met.

KG, FT	19.59	TURN SPEED, KT	26.4
		TURN RADIUS, FT	818.6

Figure 8-5. Static Stability Curve with Turn Heeling Arm.

Additionally, the Damage (Underwater flooding) Criteria must be verified as satisfactory. For ships over 300 feet in length without a side protection system, such as the RDS-2010, the ship must be able to withstand flooding from a shell opening equal to 15% of the ship's length at any point fore and aft along the length. The following items must be met to satisfy this flooding criteria: (1) the static trimmed-heeled waterline after damage does not submerge the margin line; (2) the static heel angle without wind effects does not exceed 15 degrees; (3) adequate dynamic stability exists to absorb the energy imparted to the ship by moderately rough seas in combination with beam winds (this is the area between the righting arm curve and wind heel arm curve); (4) the righting arm curve is terminated at the 45 degree point. Figure 8-6 shows the righting arm curve and wind heel arm curve for the RDS-2010 as generated by the ASSET program.

B. ARRANGEMENTS

The ship design team was tasked with completing some internal and topside arrangements. Internal space allocation level of detail arrangements were completed for all internal spaces. In addition, detailed compartment arrangements were completed for the primary Combat Information Center and the pilot house. Finally, the topside arrangements were completed, ensuring proper placement of combat system sensors and engagement elements to allow for maximum combat effectiveness.

1. Internal Arrangements

Figures 8-7 through 8-13 show the general (space allocation) arrangements of the 03 through 01 deck levels, and the main through fourth deck levels, respectively. The goal here was to ensure that sufficient space was allocated for all functions as defined by the ASSET program and to ensure that the location of these spaces met the overall ship design goals. Specific emphasis was placed on ensuring the integrity of the enclaving philosophy.

Figure 8-13. 4th Deck General Arrangements.

2. Detailed arrangement

Two spaces, the primary Combat Information Centers (CIC) and the pilot house, were arranged in detail. Figures 8-14 and 8-15 show these results.

PRI CIC U/L

PRI CIC L/L

Figure 8-14. Primary CIC Detailed Arrangement.

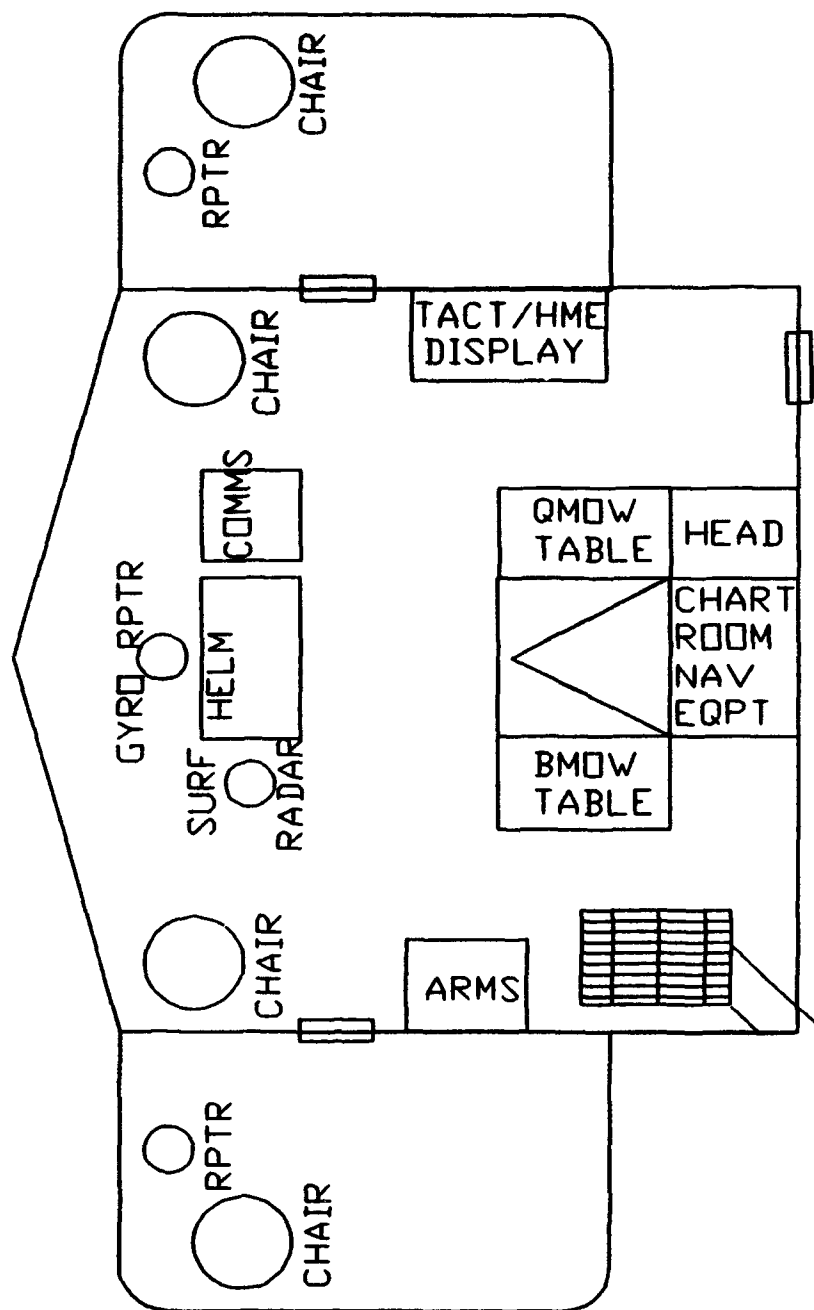

Figure 8-15. Pilothouse Detailed Arrangements.

3. Topside Arrangement

The goal in topside arrangements is to obtain a topside layout which maximizes combat system effectiveness and still allows for operational requirements. The design team felt that a need to follow a specific design process was required in order to support such a goal. The team agreed to use the following process:

- a. review mission requirements and design constraints,
 - (1) identifying elements needing to be high and
 - (2) identifying elements needing clear arcs of fire;
- b. identify required topside elements;
- c. prioritize need/satisfaction for elements;
- d. layout ship model;
- e. assess ship performance; and
- f. iterate until performance is acceptable.

Based on this process we felt that optimum locations were chosen for the topside components. Potentially competing requirements such as maintaining the enclaving scheme topside, ensuring adequate arcs of coverage for detection and engagement elements, while minimizing the overall impact on operational requirements, had to be reconciled. Figure 8-16 shows the location of the major topside components (primarily combat system detection, track and engagement elements).

During the topside arrangement phase, the arcs of coverage of the various weapons systems had to be checked for adequate coverage and minimal interference. This was done solely on a geometric scale and did not involve the use of any blockage assessment models.

C. HULL DAMAGE AND FLOODABLE LENGTH

Before a discussion of hull damage and floodable length can begin, several items must be defined for the purpose of clarity. These items are:

Bulkhead deck -- The bulkhead deck is the uppermost deck to which the transverse watertight bulkheads extend.

Margin line -- The margin line is a line drawn parallel to, and a minimum of three inches below, the bulkhead deck at the side.

Permeability -- Permeability is the percentage of volume in a space that can be flooded. It is expressed as the ratio of available volume to total volume.

Floodable length -- Floodable length is the maximum length that a given longitudinal position within a ship can be symmetrically flooded at the prescribed permeability without sinking below the margin line.

Factor of subdivision -- The factor of subdivision is an arbitrary factor applied to the floodable length to obtain the permissible length of compartments within a ship. The factor of subdivision is prescribed by national and international rules and conventions as a function of ship length and type of service. Generally, the factor of subdivision ensures that one, two or three compartments must be flooded before the ship settles to the margin line. Ships designed to these rules are sometimes called one-, two-, or three-compartment ships with reference to their damaged-stability capabilities.

Permissible length -- The permissible length of a compartment within a ship is obtained by multiplying the value of the floodable length at the center of the compartment by the factor of subdivision.

Curve of floodable length -- The curve of floodable length is a curve which at every point in its length has an ordinate representing the length of ship that may be flooded with the center of length at that point without submerging the margin line.

1. Numerous considerations are involved in determining the optimum arrangement of subdivisions for a naval combatant, but the principal factors are:

- a. ability to survive underwater damage;**
- b. protection of vital spaces against flooding;**
- c. interference of subdivision with arrangements;**
- d. interference of subdivision with access and systems;**
- e. provision for carrying liquids;**
- f. possibility of bow-collision damage; and**
- g. possibility of stranding.**

There are always conflicts among these various factors, hence their relative importance must be determined.

For the design of RDS-2010 the first four factors were considered to be most important thereby driving the design to have transverse bulkheads placed as shown in Figure 8-20. The standard rule used by the U.S Navy for floodable length calculations is that the ship be able to accept damage to the hull which results in an opening to the sea of fifteen percent of the length between perpendiculars without submerging the margin line. This value for the RDS-2010 is 58.5 feet. This means that the design must accept a damage length of 58.5 feet anywhere in the hull. This damage length requires that the RDS-2010 be a four-compartment ship.

2. Referring to Figure 8-20, it is seen that for a continuous permeability of 0.95 the design meets the required damage length and is in fact a four-compartment ship. If the permeability of each subdivision was updated to the actual value, the floodable length curve would move upward resulting in larger floodable lengths, improving the apparent survivability of the design. The plot of the floodable length curve shown in Figure 8-20

depicts the worst case scenario (total ship permeability equal to 0.95) to ensure that the design criteria were met.

Reference [5] provides more information on the construction of a floodable length curve.

Figure 8-20. Floodable Length Curve.

D. SHIP STRUCTURE REPORT

1. Ship Structural Loads

The size and principal characteristics of a ship are determined primarily by its mission, intended service, and cost. In addition to basic functional considerations there are requirements such as stability, low resistance and high propulsive efficiency, good sea keeping, and navigational limitation on draft or beam, all of which influence the choice of dimensions and form. The ship's structure must be designed, within these and other basic constraints, to sustain all of the loads expected to arise in its seagoing environment. In contrast to land based structures, the ship does not rest on a fixed foundation but derives its entire support from buoyant forces exerted by a dynamic and ever changing ocean environment, which is both the friend and enemy of the ship.

The structural components of a ship are frequently designed to perform a multiplicity of functions in addition to that of providing the structural integrity of the ship. Furthermore, many strength members serve dual functions. For example, bulkheads that constitute substantially to the strength of the hull may also serve as watertight boundaries of internal compartments. Their locations are dictated primarily by the required tank volume or subdivision requirements.

The loads that the ship structure must be designed to withstand have many sources. There are static components which consist principally of the weight and buoyancy of the ship in calm waters. There are dynamic components caused by wave induced motions of the ship, and by slamming or springing in waves, as well as vibratory loads by the propeller and machinery, all of which range over different frequency ranges. An important characteristic of these load components is their variability with location and time (North Atlantic conditions in January are far from being the same as Mediterranean in July), and with the particular voyage (lightship versus fully loaded conditions).

Furthermore, the loads imparted by the sea are random in nature, and therefore the ship's structural behavior can be expressed only in probabilistic terms.

a. Four principal mechanisms are recognized as causing most of the cases of ship structural failure, aside from collision or grounding. These modes of failure are as follows:

- (1) excessive tensile or compressive yield;
- (2) buckling due to compressive or shear instability;
- (3) fatigue cracking; and
- (4) brittle fracture.

The problem of ship structural design then consists of the selection of material types, frame spacing, frame and stiffener sizes, and plate thicknesses, becoming an integrated part of the design spiral.

b. It is convenient to divide the loads acting on the ship structure into four main categories, based partly upon the nature of the load and partly upon the ship's response:

(1) Static loads are loads that change only when the weight of the ship changes. These include:

- (a) weight of the ship and its contents;
- (b) static buoyancy of the ship at rest or in motion;
- (c) thermal loads resulting from temperature gradients within the hull; and
- (d) concentrated loads caused by dry docking or grounding.

(2) Low frequency dynamic loads are loads that vary in time with periods ranging from a few seconds to several minutes, therefore they do not result in any

appreciable resonant amplification of the stresses induced in the structure. These can be broken down into the following components:

- (a) wave induced hull pressure variations;
- (b) hull pressure variations caused by transient ship motions;
and
- (c) inertial reactions resulting from the acceleration of the mass of the ship and its contents.

(3) High frequency dynamic loads are time varying loads of sufficiently high frequency that they may induce vibratory response of the ship structure. Some of the exciting loads may be quite small in magnitude but, as a result of resonant amplification, can give rise to large stresses and deflections. Examples of such dynamic loads include the following:

- (a) hydrodynamic loads induced by propulsive devices;
- (b) loads imparted to the hull by reciprocating or unbalanced machinery;
- (c) hydrostatic loads resulting from interaction of appendages with the flow past the ship; and
- (d) wave induced loads due primarily to short waves whose frequency of encounter overlaps the lower natural frequencies of hull vibration, called *springing*.

(4) Impact loads are loads resulting from slamming or wave impact on the bow, including the effects of green water on deck. In a naval ship, weapon effects constitute a very important category of impact loads. Impact loads may induce transient hull vibration that is called *whipping*.

c. The most important classes of loads are the static loads resulting from the ship's weight and buoyancy, and the low frequency dynamic loads, while springing loads are important in very long flexible ships such as the Great Lakes carriers. In addition to the above four main categories, there may exist specialized operational loads, which may be the dominant loads for certain ship types. Examples of such loads, which may be either static or dynamic, are:

- (1) ice loads in the case of a vessel intended for ice breaking or Arctic navigation;
- (2) loads caused by impact with other vessels, as in the case of tugs and barges;
- (3) impact of cargo handling equipment;
- (4) structural thermal loads imposed by special cargo carried at extreme temperature and/or pressures;
- (5) sloshing and impact loads on internal structures caused by movements of liquids in tanks; and
- (6) aircraft or helicopter landing forces.

2. Static loading.

The two main categories involved in static loading are the weight of the hull and its components and buoyancy, as shown in Figure 8-21. The individual loads may have both local and overall structural effects. A very heavy piece of machinery induces large local loads at the points of attachment to the ship; therefore its foundation must be designed to distribute these loads evenly into the hull structure. Simultaneously, the weight of this piece of machinery contributes to the distribution of shear forces and bending moments acting along the length of the hull.

Figure 8-21. Static loads and structural response.

The geometrical arrangement and resulting stress and deflection patterns of typical ship structures are such that the associated response is usually divided into three components, as shown in Figure 8-21. The primary response is the response of the entire hull, when bending and twisting as a beam, under the external longitudinal distribution of vertical, lateral, and torsional loads. Study of this response constitutes the longitudinal strength calculations and are usually performed in ship structural analysis and design. The secondary response comprises the stress and deflection of a single panel of stiffened plating. The loading of the panel is normal to its plane, and the boundaries of the secondary panel are usually formed by other secondary panels, such as side shell and bulkheads. The tertiary response describes the out of plane deflection and associated stress of an individual panel, and its boundaries are formed by the stiffeners of the secondary panel of which it is a part. The last two responses can be evaluated using the familiar laws of structural member response from solid mechanics.

A typical longitudinal distribution of weight and buoyancy for a ship afloat in calm water is illustrated in Figure 8-22. In the lower part of this figure is plotted a curve (1) of buoyancy force per unit length, which is equal to the weight density, ρg , of the water times the sectional area. For any waterline shape, the buoyancy curve can be easily obtained from the Bonjean curves. The upper curve (2) of Figure 8-22 shows the longitudinal distribution of the weight force, which essentially consists of a book-keeping process in which every item aboard the ship is recorded and assigned to a particular location. The total load acting on the ship is

$$f(x) = b(x) - w(x),$$

where $b(x)$ is the buoyancy per unit length, and $w(x)$ the weight per unit length. The conditions for static equilibrium require that the integral of the total load over the ship length and the integral of the longitudinal moment of the load curve each be zero. As in

standard beam calculations, the shear force at some location x , is equal to the integral of the load curve,

$$V(x) = \int_0^x f(x) dx;$$

and the bending moment is the integral of the shear force

$$M(x) = \int_0^x V(x) dx.$$

It can be observed that the shear force and bending moment are zero at the bow and the stern, as they ought to be since the ship is essentially a free-free beam resting on an elastic foundation. Besides the still water buoyancy curve at the design waterline, two other conditions are traditionally studied, as shown in Figure 8-22. The first is that of a wave of length equal to the length of the ship located with its crest at amidships, and this condition is called *hogging*. The second wave condition traditionally studied is that of a wave whose trough is located amidships, and this condition is called *sagging*. Although no dynamic affects are considered in the sagging and hogging conditions, they can be used to provide extreme loading conditions for comparative or design purposes when combined with the appropriate ship loading condition.

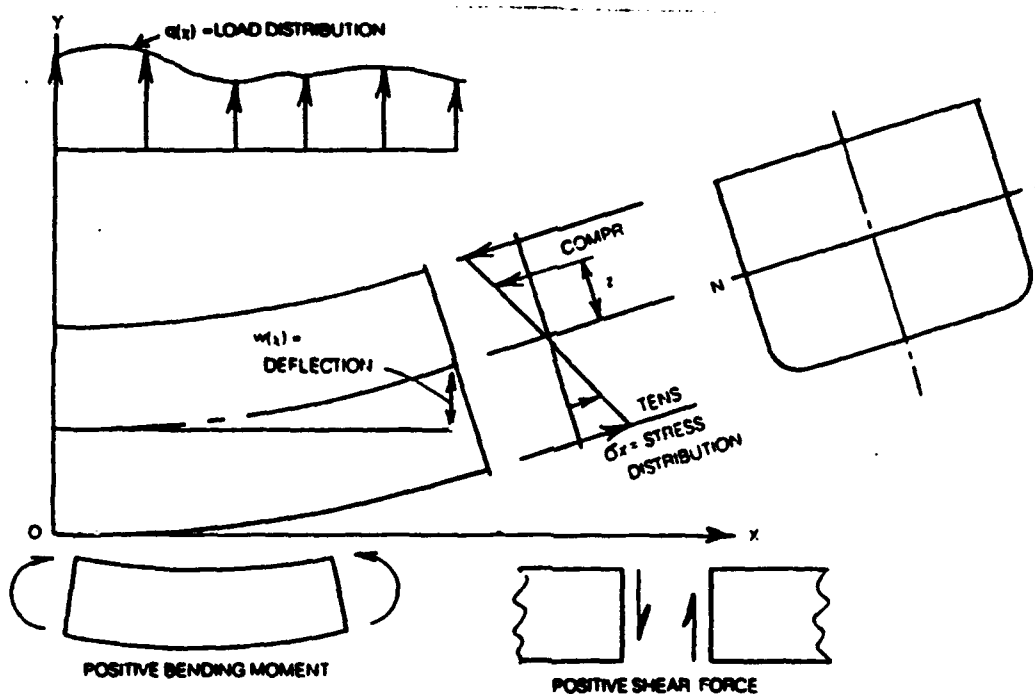

Figure 8-22. Static loads, shear, and bending moment.

3. Wave induced loading.

The principal wave induced loads are those previously referred to as low frequency dynamic loads or loads involving ship and wave motions that result in negligible dynamic stress amplification. The calculation of the bending moment, shear force, and torsional loading on a ship hull due to waves requires a knowledge of the time varying fluid pressure distribution over the wetted surface of the hull together with the distribution of the inertial reaction loads. The fluid loads depend on the wave induced motions of the water and the corresponding ship motions, which in turn depend on the fluid loads. One popular solution to this complicated problem involves the use of *strip theory*, where the ship is divided into narrow transverse strips. This allows the reduction of a three dimensional problem into a family of two dimensional problems that are easier to solve. The results then are integrated along the length of the hull.

a. One of the important assumptions of linear strip theory is that both the wave and ship motion amplitudes are, in some sense, small. As a result it is possible to consider the total instantaneous vertical force on a thin transverse strip to be composed of the sum of several terms that are computed independently of each other. Two of these forces are the still water buoyancy and weight of the element of the ship length, in other words the static loads from the previous section. The remaining forces are time varying and result from inertial reaction and from the water pressures, and can be divided into the following categories:

(1) A wave pressure force component computed as though the presence of the ship does not disturb either the incident waves or the dynamic pressure distribution in those waves. This is called the *Froude-Krylov* force.

(2) A wave pressure force component computed from the properties of the diffracted wave system. These waves result from the reflection and distortion of the

incident waves as they impinge upon the ship, and is called the *diffraction* force. Together with the Froude-Krylov force, it is sometimes referred to as the *wave exciting* force.

(3) A term proportional to the instantaneous vertical displacement of the ship strip from its mean position, as if in calm water. This is called the *hydrostatic* restoring force and is equal to the change in the mean static buoyancy of the element.

(4) A term proportional to the instantaneous vertical velocity of the element, called a *damping* force.

(5) A term proportional to the instantaneous vertical acceleration of the element called an *added mass* force. The added mass and damping forces are also known as the *radiation* forces since as a result of the ship motions, a wave system that radiates away from the ship is generated.

The first two of the above forces are computed as though the ship moves steadily forward through the waves but experiences no oscillatory motion response to the wave forces. The last three forces are computed as though the ship is undergoing its oscillatory wave induced motion while moving at a steady forward speed through calm water. Within the assumptions and limitations of linearity, such a breakdown is permissible.

In addition to the sum of the above forces $q(x)$, there must be added the inertial force $-m(x)a_v$ per unit length, where $m(x)$ is the mass of the strip and a_v is the vertical absolute acceleration of the ship strip. The wave induced loading per unit length is then

$$f_w(x) = q(x) - m(x)a_v,$$

and the wave induced shear force and bending moment are obtained by successive integrations of the load.

Figure 8-23 illustrates the different components of the load distribution at a fixed time for a typical Mariner class cargo ship moving through a simple sinusoidal wave

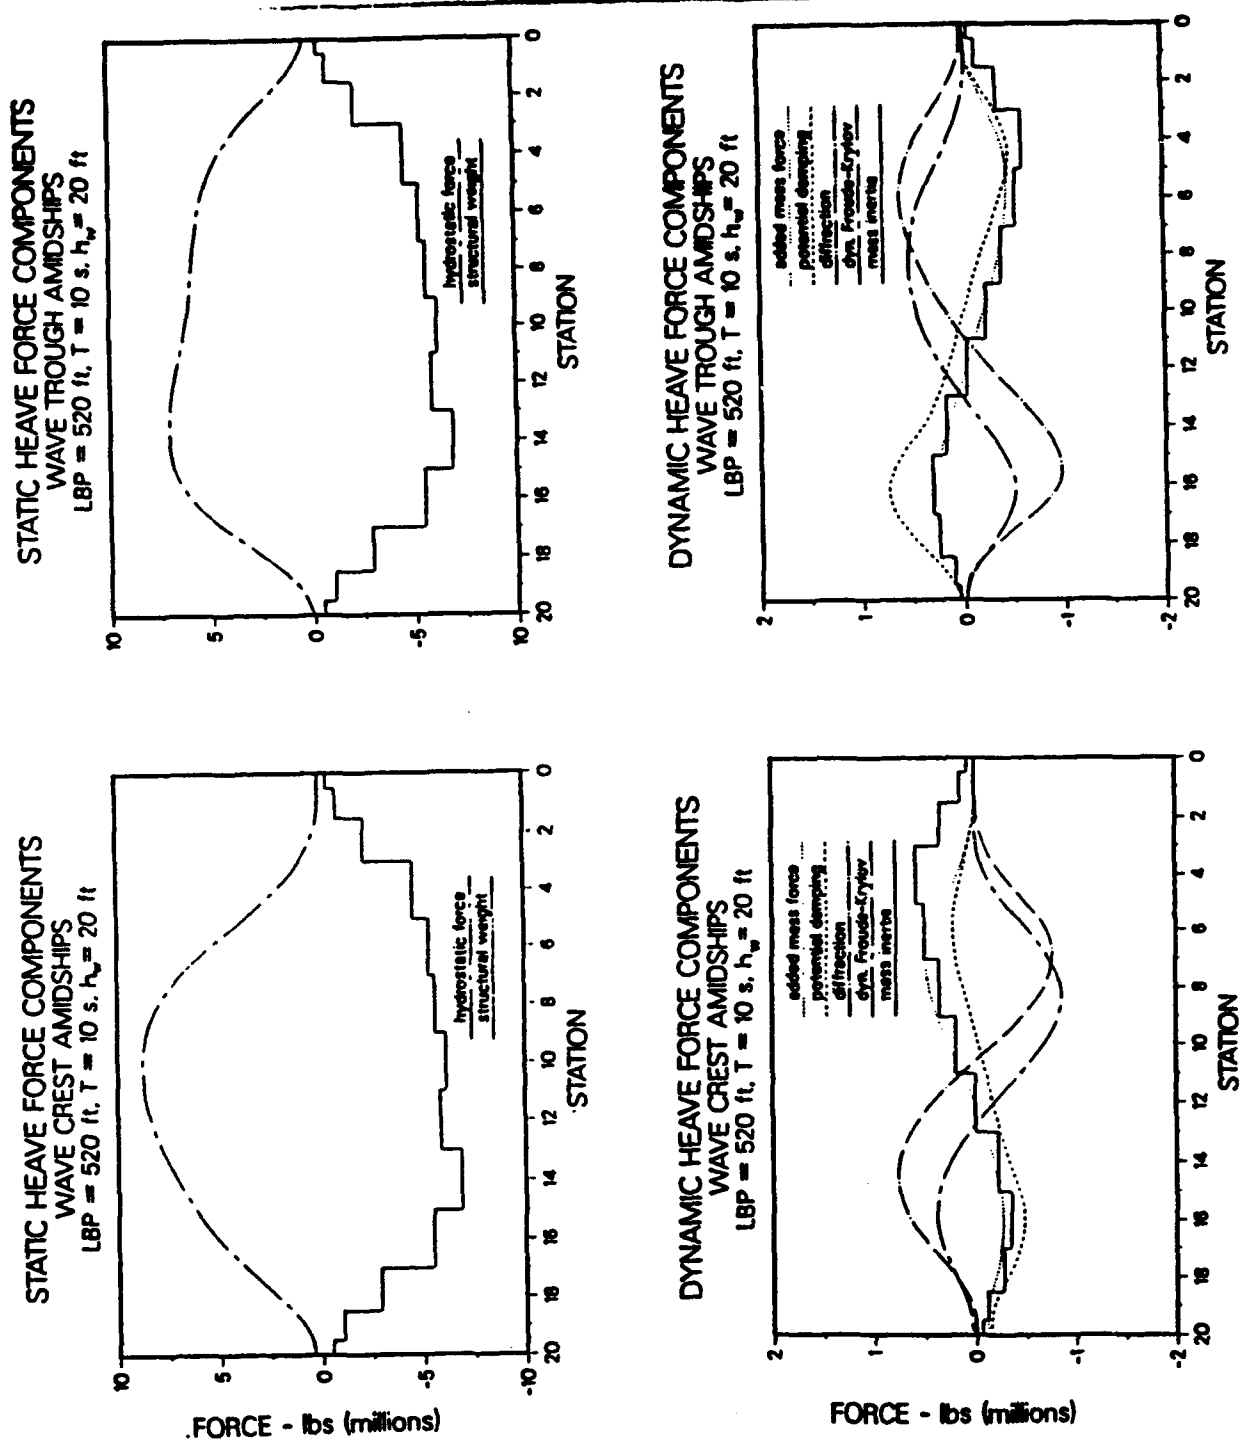

Figure 8-23. Typical wave induced ship loads.

of unit amplitude. We can see that the total loading consists of a number of tears of similar magnitude which may differ in sign and phase. There may be cancellation or reinforcement among the different components, with the result that the total loading may be larger or smaller than any individual component. This cancellation or reinforcement varies along the ship length and also varies with the frequency of wave encounter.

Although the above discussion was made with a view towards vertical ship motions (heave and pitch), a similar concept can be applied for the horizontal motions (sway and yaw). The transverse distribution of wave loads is also necessary to compute the secondary or tertiary response of structural components such as panels of stiffened or unstiffened plating.

b. Finally, the above deterministic load can be extended through the use of statistical analysis techniques, to reflect the probabilistic nature of wave loads. The statistical quantities that are usually of concern in ship strength investigations are divided into three categories:

(1) *Short-term mean and extreme values.* These refer to the period of time of a few hours during which the sea remains statistically stationary under normal climatic conditions.

(2) *Long term mean and extreme values.* These refer to a longer time period, days or years, during which the sea state may vary widely from calm to severe storm conditions. The long term response may be thought of as an accumulation of short term responses to different sea states, each having uniform or statistically stationary characteristics.

(3) *Cumulative cyclic values.* These refers to long term cyclic loading that may cause fatigue damage to the structure, even under moderate to low level of bending moment and stress.

B. LONGITUDINAL STRENGTH.

The term longitudinal strength refers to the overall structural behavior of a ship as a thin walled hollow beam under the influence of the previously mentioned bending moment and shear forces. Longitudinal strength calculations are predominantly used for midship section synthesis and the overall ship structural integrity evaluation.

In simple beam bending theory used in basic ship structural analysis, the following assumptions are made:

1. Kinematic assumptions from elementary Euler-Bernoulli beam theory, which neglect the bending from shear effects. The kinematics describe the deformation of the beam without regard to the forces on the beam.

a. Plane sections remain plane before and after deformation, no shear or warping.

b. Plane sections normal to the line of centroids remain normal before and after deformation, no shear. These two assumptions mean that $\gamma_{xy} = \gamma_{yx} = 0$.

c. Strains are sufficiently small so that the cross sectional geometry does not change; no Poisson effects. This means that $\epsilon_y = \epsilon_z = \gamma_{yz} = 0$.

d. Beam slopes are small.

e. Beam cross section is prismatic. This is optional but is usually the case in ship structures.

2. Physics assumptions describe the material behavior.

a. The material obeys Hooke's law; force is linearly proportional to displacement.

b. The material is isotropic (has the same properties in every direction at one point) and homogeneous (material properties are the same at all points) in the y-z plane.

c. Stress field is one dimensional, the only significant stress is along the x -axis of the beam.

A sketch of the coordinate description and the positive bending moment convention is shown in Figure 8-24. The x -axis defines the centroid of the cross section provided the first moments of area are zero

$$\int_A y dy dz = \int_A z dy dz = 0.$$

For homogenous cross sections, the centroidal axis is the same as the *neutral* axis in bending, which is defined as the line or plane of zero strain. The differential equation for the elastic curve for a symmetrical beam is

$$EI_y w'' = M(x),$$

where w is the deflection, E the Young's modulus of elasticity of the material, I_y the second moment of area of the beam cross section around the y -axis through its centroid, and $M(x)$ the bending moment.

In terms of the load per unit length $f(x)$, the equation can be written as

$$EI_y w'''' = f(x).$$

Solution of this equation by multiple integrations, requires four boundary conditions, and since the ship is a free-free beam, these are zero shear and moment at the two end points.

The longitudinal stress at station x is related to the bending moment by

$$\sigma_x = -\frac{M(x)}{I_y} z,$$

where z is the vertical distance from the neutral axis. From the above equation it is clear that the extreme stresses are found at the top or bottom of the beam where z takes on its numerically largest values. For a positive bending moment, the top of the beam is in compression and the bottom is in tension.

Figure 8-24. Coordinate description and sign convention.

One variation of the above beam equation is of importance in ship structures. It concerns beams composed of two or more material of different moduli of elasticity, for example, steel and aluminum, which may be between the main hull and superstructure. In this case, the flexural rigidity EI , is replaced by the integral $\int_A E(z)z^2 dA$, and the neutral axis is located at a height such that

$$\int_A E(z)z dA = 0.$$

From the previous stress equation it can be seen that there is a discontinuity in the stress distribution, whereas the strain, $\epsilon_x = \sigma_x / E$, will be continuous where two different materials join.

C. RDS 2010 ANALYSIS

A detailed structural analysis was performed on the RDS 2010, using the structural module contained in the ASSET program and is presented in the Feasibility Output Report, included as Appendix D. Detailed buoyancy, weight and load curves were produced using information from the ASSET output and are presented in Figure 8-25. The buoyancy curve was computed by converting the sectional area curve to a force per length curve by dividing the respective areas, at each station, by 35 tons/ft³. The weight distribution curve was developed by using the one digit weight groups and their respective LCG's from the ASSET output, and converting them into uniform loads centered about their LCG's. The load curve was developed by taking the difference between these two forces. As Figure 8-25 displays, there are two critical points, located at the ship's quarters, that must be analyzed more fully in the later portions of preliminary design. The sharp load changes at these points may be reduced when a more detailed weight distribution is known. Once this updated weight distribution is developed, and these points still present a

problem, the hull will have to be reinforced near the area of the critical points to compensate for the sharp changes in load.

Figure 8-25. Still water force curves.

Figures 8-26 and 8-27 display the buoyancy, weight and load curves for the hogging and sagging conditions respectively. The two buoyancy curves for the two quasi-static conditions of hogging and sagging were developed by constructing Bonjean curves for the hull form, and balancing the hull on a trichoidal wave of the correct length and height. Due to the tools available to complete this task, and the time available, the hull form was not exactly "balanced" on the wave. The difference between the areas under the buoyancy and weight curves for the two cases is on the order of five percent, at most. The difficult task was to achieve equilibrium by aligning the centroids of the areas beneath the respective curves. The inability to achieve this equilibrium caused the shear force and bending moment curves to yield erroneous results.

Figure 8-26. Hogging condition force curves.

Figure 8-27. Sagging condition force curves.

As Figure 8-28 shows, the shear force and bending moment curves do not return to zero at the end of the ship. This error would be alleviated if the centroids of the respective areas could be aligned. Although the curves do not correctly represent the shear force and bending moment, the maximums of these are of the order needed for design purposes.

Using an early estimate for midship section design, the required design bending moment can be determined. The empirical formulas available to obtain this estimated moment are;

$$M = \frac{\Delta L}{C},$$

where C represents a constant depending on the ship type and bending condition (hogging or sagging);

$$BM_H = 0.000457(LBP)^{2.5} B$$

for the hogging condition;

$$BM_S = 0.000381(LBP)^{2.5} B.$$

A typical value of C for a ship of this type is approximately 30, for both bending conditions.

Using these equations, the design bending moment is approximately 80,000 FT-LTON. As Figure 8-28 displays, the bending moment using the erroneous curve is approximately 200,000 FT-LTON in still water. If the same bending moment curve was plotted for the hogging and sagging conditions it would be shown that the maximum bending moment value is approximately 250,000 FT-LTON. Further refinement of the weight distribution curve would bring these results closer to the estimated bending moment.

Figure 8-28. Still water force and bending moment curves.

D. MIDSHP SECTION DESIGN

The midship section was designed, through thousands of iterations using the ASSET Hull Structures Module, and is shown in Figure 8-29. Information concerning the size and placement of scantlings and stiffeners can be found in the ASSET Feasibility Output Report, Appendix D.

Figure 8-29. RDS 2010 Midship section design..

IX. DESIGN EVALUATION

Once the feasibility studies and preliminary design phase have been completed, the design team must step back and perform an evaluation of design efforts to date. The design is assessed in a number of ways, based on top level design specifications and mission requirements:

- 1) The ship meets stated performance goals including
 - (a) speed, endurance, and other performance based attributes; and
 - (b) systems installed to perform designated missions.
- 2) The ship meets given cost and 'political' goals.
- 3) The ship meets stated survivability goals.

The first two elements above are actually part of the iterative design process. Assuming that the design requirements and goals were clearly stated and then implemented, then the design process will constantly revisit whether the design matches the original set of requirements. For instance, using the ASSET program, one input is desired cruising speed. The ship design which ASSET produces is iterated until this performance goal is met. Other performance based attributes are similarly met during the ASSET iterative cycle.

During the combat system definition process, the threat scenarios were evaluated to ensure the combat system was adequate. This included not only the systems installed, but numbers of engagement elements and number of rounds required.

The cost goal was not met, but the faculty raised to cost ceiling based on our analysis and the desire not to give up critical capabilities of the ship. The "political" goals are more subjective, as equally hard to design to as they are, to evaluate the success of meeting them.

The last item, meeting stated survivability goals still needs to be assessed in some manner, however. The total ship survivability assessment is divided into four phases:

- 1) *Cover and Deception* - the ability to remain undetected or prevent the enemy from obtaining a fire control solution accurate enough to launch a weapon
- 2) *Threat Destruction and Evasion* - the ability to intercept and destroy or divert threat weapons
- 3) *Damage Tolerant Design* - addresses the loss in mission capability due to weapons impact
- 4) *Damage Control and Repair* - addresses the ship's ability to recover mission capability lost due to the weapons hit

Note that the first two items are what is typically called the susceptibility, whereas the last two deal with the ship's vulnerability.

A low design priority was given to the cover and deception aspects for the most part. This is due to the ship's mission of operating close to shore. There was a conscious effort to reduce the ship's infrared and radar cross-sections, however. Oversized stacks were designed to reduce the gas turbine exhaust temperatures. Shaping of the ship's superstructure was done to reduce RCS. There is, however, no way for the design team to evaluate the effectiveness of these efforts.

The threat destruction and evasion capability is directly related to the types and numbers of defensive weapons placed on the ship. As shown in Chapter 4, threat scenario evaluations were completed in the AAW warfare area to ensure adequate numbers and types of AAW engagement elements. Similarly analysis still needs to be performed for the ASUW and ASW warfare areas.

The tolerance of the design to battle damage is addressed by the enclaving scheme and associated systems architectures. Similarly, the ability of the ship/crew to control and

repair damage is directly related to the physical design attributes of the ship, including the survivability management system and automated damage control systems. Again, however, there is no firm method for the design team to assess the performance of these concepts.

The tools to evaluate the ship's systems readiness and survivability are:

- 1) readiness logic diagrams (RLDs);
- 2) system deactivation diagrams; and
- 3) physical arrangements of the ship.

The system deactivation diagrams are necessary and appropriate for detailed analysis for cause and effect of damage on specific elements and systems. However, the complexity of this approach precluded the design team from using this tool.

The design team did, however, develop a set of RLDs at the first level of detail for four mission areas (AAW, ASUW, ASW, and MOB). These were combined with the physical layout of the ship to perform a ship system survivability assessment at the enclave level of detail.

The RLDs were developed based on the required operational capabilities (ROCs) by mission/warfare category and the actual systems designed into the ship. Figures 9-1 through 9-4 show the RLDs for the AAW, ASUW, ASW, and MOB mission areas, respectively.

The "M" and "C" readiness rating levels apply to warfare and composite areas, respectively. Table 9-1 shows the relative definition of the mission readiness rating levels. The level indicates the readiness level rating due to a component or mission area

Figure 9-1. AAW Readiness Logic Diagram.

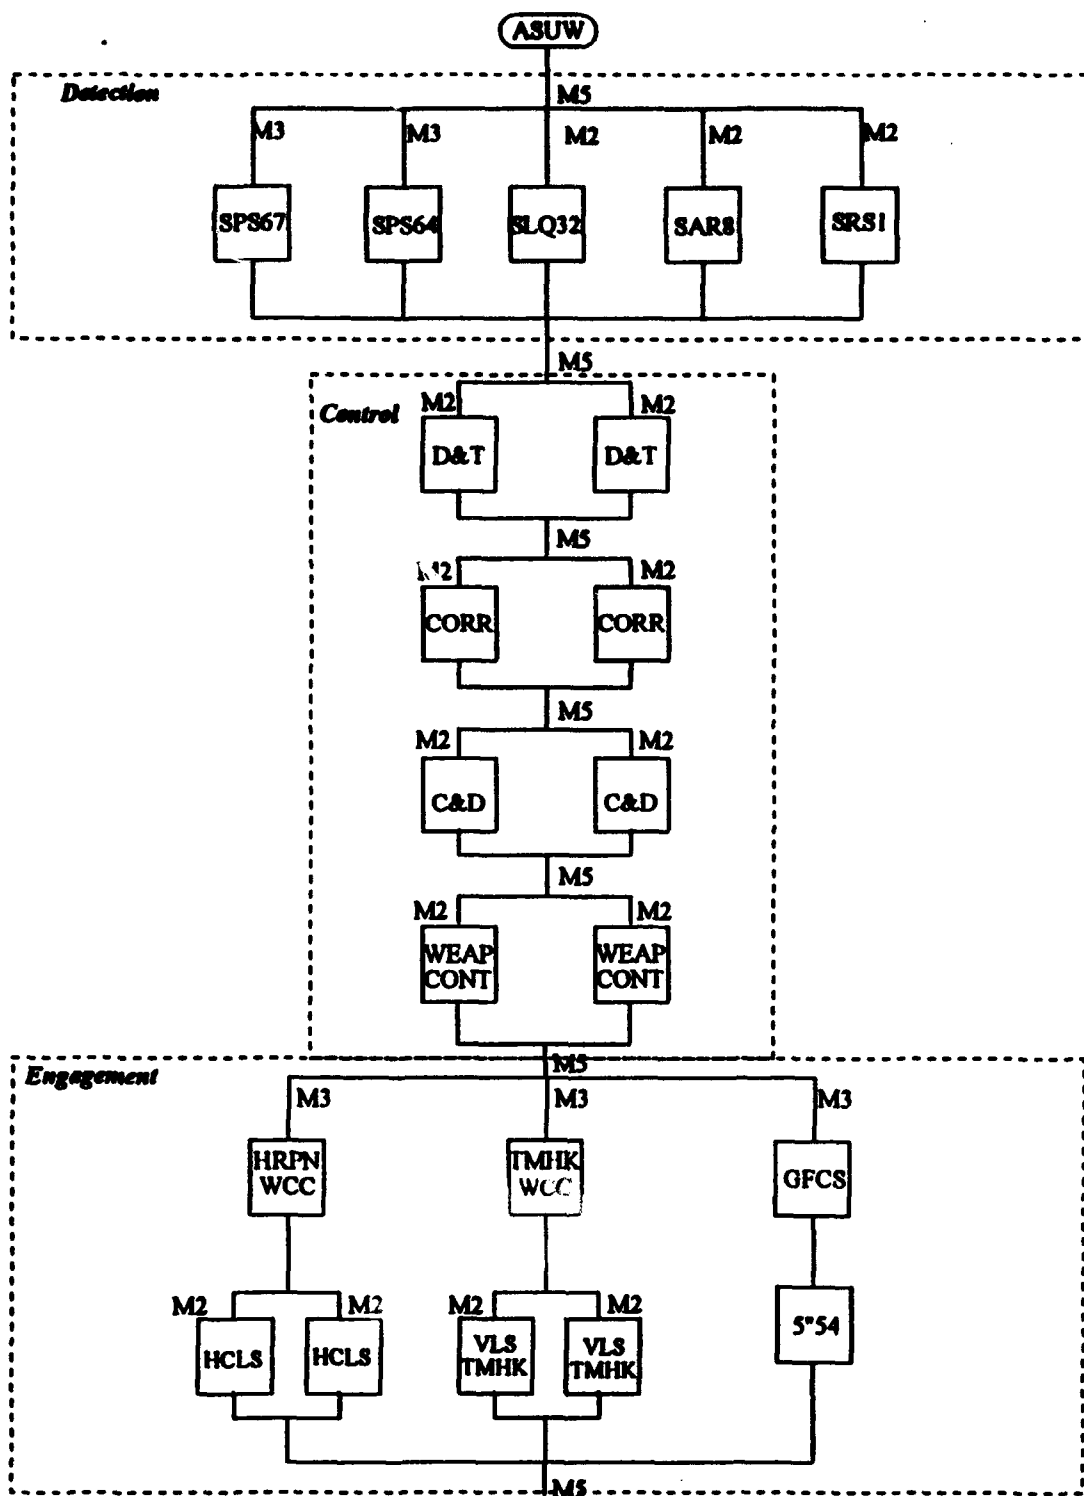

Figure 9-2. ASUW Readiness Logic Diagram.

Figure 9-3. ASW Readiness Logic Diagram.

* M value for loss of all functionality within one enclave only

Figure 9-4. Mobility Readiness Logic Diagram.

loss. The lower level values are rolled-up to produce the higher level values, and finally the composite scores.

TABLE 9-1. MISSION READINESS RATING LEVEL DEFINITIONS.

<i>Rating Level</i>	<i>Capability</i>
M1, C1	90-100%
M2, C2	70-89%
M3, C3	60-69%
M4, C4	1-59%
M5, C5	No Capability

Using these RLDs in conjunction with a physical layout of the ship, an enclave level readiness assessment was completed. This assessment reveals the ship's readiness condition due to the loss of a single enclave. Loss of an enclave means the loss of all elements functionality contained within the enclave (i.e., if the No. 1 Mk-92 is within enclave 2, then loss of enclave 2 means loss of any capability associated with the No. 1 Mk-92). Loss of an enclave does not decimate all system pass through capability, however. The assumption is that due to the redundancy designed into systems such as electrical distribution, fiber optic ring bus, fire main water, high pressure air, etc., that at least partial pass through capacity remains short of catastrophic ship damage. Any damage which is so severe to destroy not only all elements within an enclave, but also destroy all systems which merely pass through the enclave would likely result in immediate ship loss.

Within each enclave, each mission area (AAW, ASUW, ASW, and MOB) was evaluated using the RLDs to see what each area's readiness assessment score ("M" rating) was upon loss of the systems within that enclave. The individual mission area ratings were

then rolled-up into a composite score to reveal the ship's total readiness condition resulting from loss of the enclave.

Figure 9-5 illustrates these results. Note that the ship is fairly well balanced, with each enclave loss resulting with a ship's composite score of C3. The exception is loss of enclave 5. The C5 rating for enclave 5 is due to the assumption that both screws are lost if enclave 5 is lost, resulting in total loss of propulsion. Arguments may be made that from an operational sense, loss of all propulsion does not result in a zero capable ship. From a combat system vantage, loss of enclave 5 only degrades the ship to a C3 level. This argument cannot be resolved until there is reconciliation between the present method of reporting readiness and a more appropriate scoring method usable for real-time, from the scene ship's readiness assessment reporting.

Figure 9-5. Enclave level survivability assessment.

A through D

DESIGN HISTORY

28 SEP 92 TS4002/4003 course sequence introduction given by Professors Charles N Calvano and Francis B Fassnacht. The design team consists of LCDR Dwight Alexander, LCDR Dean Cottle, LT Kent W. Kettell, and LT Jeff Riedel. Received a CNO Tentative Requirement Statement, written in operational/political terms for a new class of surface ship, FPS 2010. As a review of requirements determination and setting, the first objective is to assist the CNO in developing a formal acquisition requirements statement with which he can task NAVSEA to design and procure the ships.

29 SEP 92 It was agreed upon by the design team that LT Kettell would be the design team coordinator.

07 OCT 92 The design team completed the "Requirements Document for Force Projection Ship (FPS) 2010". The requirements were written such that the ship would not be required to conduct ASW screening operations during Battle Group transit. Additionally, it was not considered necessary for the FPS 2010 to capable of long range AAW.

08 OCT 92 The Force Projection Ship 2010 is renamed Regional Deterrence Ship (RDS) 2010, and the "Requirements for Regional Deterrence Ship (RDS) 2010" is released by the CNO (faculty) with a few major changes other than the name:

- 1) The ship is not required to deploy promptly, fully ready for extended operations.
- 2) The time on station reduced from 60 days to 20 days.
- 3) The ship would be required to support short duration covert operations.
- 4) The combat system would incorporate an appropriate SSSES.
- 5) The ship should support flight operations of non-assigned joint forces helicopters.
- 6) The ship will carry a surgeon and have operating room facilities.

Additionally, it was clarified that approximately 10 of the RDS ships would be built.

Since to date there has been no clear recognition of specific threats for which the design team should be concerned when designing the combat system, it was agreed to that a list of most formidable threats would be generated prior to completing selection of the major ship elements.

19 OCT 92 Design team completed the major threat evaluation. This was a lengthy process in which the design team assumed the role of intelligence experts and determined the air launched, surface launched and sub-surface weapons which were deemed to impose the greatest threat. The process was lengthy in spite of the fact that sufficient information does not exist in the open literature. The parameters which seemed worthy of comparison were radar cross-section, speed, range, warhead size, guidance type and the profile of the trajectory. In the air and surface launched missile categories the plan to determine the most formidable threats was as follows:

- a) three with the smallest radar cross-section,
- b) three with the fastest speed,
- c) three with the longest range, and
- d) three with the largest warhead.

In a few cases there was overlap, but generally this provided a worthy selection for later evaluation. The next step was to eliminate some of the threats based on simple comparison with others within the same category. At this point there remained only ten missiles which were significantly threatening in one way or another. This is shown in Table I. The torpedo threats were determined in a similar manner using speed and range. The mine size was determined based on the need to detect mines of this size in order to maneuver around them in sufficient

time in order to prevent either influence or contact. The mines smaller than this size were deemed to be less threatening based on the amount of explosive potential. To whittle the missile list down to a most fearsome four, the type of guidance package and the profile of the trajectory were considered. To account for advances in technology some of the characteristics of two weapons were merged to give a margin of safety. The missiles used therefore do not represent actual missiles, but ones very similar to actual ones. For security purposes the real

names are not used and the categories do not necessarily portray exact values, however they are realistic.

22 OCT 92 Element selection rough draft was completed. It is apparent that some elements which do not currently exist will be needed in order to build a ship which has been designed at the total ship level, looking at the entire combat system. The combat system needs to be designed at the mission level in order to achieve a completely integrated shipboard combat system. At this time many new combat system elements can not be readily integrated into the shipboard combat system, reducing the performance that was expected. It is expected that some current system elements may have to undergo major modification in order to make them compatible in a systems sense.

06 NOV 92 Revised element selection portion of the analysis and tradeoff study is complete to the point of having a definitive threat scenario. Optimally, threat scenarios as related to ship design could very well encompass a whole course.

10 NOV 92 Completed initial round of threat scenario with basic elements. With this completed, the element selection process can be finalized.

12 NOV 92 Decision matrices for threat evaluation finalized.

13 NOV 92 Specific element selection process complete, although there may be continued tradeoff analyses performed in future work in order to accommodate the price margin. Next step is to present this material in a meaningful way.

17 NOV 92 Rough final draft of the results of the specific element selection analysis and tradeoff study completed. Commenced the feasibility process using the ASSET program. The abbreviated documentation of this program is sketchy.....terminals not working well for present system configuration....

19 NOV 92 Rough draft of the threat scenarios completed.

20 NOV 92 Adjustments made to specific element selection in order to accommodate the four threat scenarios. No fleet guidance was available for determining the minimum required loadout of weapons. Since this deterrence ship will be operating alone, it should be capable of defending itself in the four threat scenarios discussed while either help is coming from other regions or it makes a retreat to a less threatening environment.

24 NOV 92 All aspects of specific element selection complete, including the paperwork.

Received documentation for use of ASSET. Volume 1, the system manual provides good insight as to how the program should be used. Volume 2(A-E) must also be used in order to make decisions regarding how the envisioned ship will be constructed, outfitted, manned, and operated.

25 NOV 92 Completed revised draft of threat scenario.

04 DEC 92 Successfully completed an initialized feasible ship. The next step is to get the modules to converge individually so the synthesis portion of ASSET will be capable of running to convergence.

07 DEC 92 Convergence achieved on ASSET synthesis model. Although the ship does not have all the same characteristics of the envisioned ship, the concept is predicable. The factors which affect a cost and stability will have to be optimized in order to determine if the ship is buildable at the requested price. In 2010 dollars, it seems that a small patrol boat may not even be economically feasible for \$350 million.

11 DEC 92 Final draft of threat scenario complete. Because of the details involved in the tedious calculations, this paper was made readable for those individuals not having received prior experience in threat probabilities as applied to scenarios such as these..

17 DEC 92 Commenced effort to reduce cost to \$350M.

06 JAN 93 Began drafting a detailed design philosophy which would provide a concrete basis for backing trade-off decisions

07 JAN 93 Commenced work on the general combat system architecture.

15 JAN 93 Completed the formal design philosophy.

20 JAN 93 Reached point of diminishing returns on cost reductions to reach the stringent \$350M limit. Began draft of cost adjustment proposal. Stopped working with ASSET, and began working with AUTOCAD for the creation of a 3-D hull and superstructure.

21 JAN 93 Commenced enclaving effort in order to best locate systems and elements throughout the ship.

25 JAN 93 Decided to include the Integrated Readiness Assessment and Survivability Management Requirements as part of the Combat System Architecture.

08 FEB 93 Enclaving progressing such that topside layout must undergo several iterations before below decks enclaving can resume.

10 FEB 93 Commenced work on "Ship Descriptors".

16 FEB 93 Enclaving at the point where below decks arrangements can begin. Commenced drafting ROCs to be used in survivability assessment. In hindsight, the design team agreed that this portion should have been done much earlier had the usefulness of this type of document been understood.

18 FEB 93 Completed the General Combat System Architecture, including the one-line connectivity diagram, battle organization, and manning structure.

19 FEB 93 Commenced electrical system design.

01 MAR 93 ROCs finalized so that survivability assessment can proceed through RLDs.

04 MAR 93 Completed electrical system design.

05 MAR 93 Began making slides for design presentations.

08 MAR 93 Arrangements completed after several iterations, enclaving verified from keel to masts.

09 MAR 93 Completed survivability assessment. The ship is very well balanced.

12 MAR 93 Completed "Ship Descriptors" portion of design.

18 MAR 93 Formal presentation of ship design to Naval Postgraduate School.

23 MAR 93 Formal Washington, DC presentation of ship design to NAVSEA 05 at NC3, Crystal City.

08 APR 93 Formal presentation of ship design to Monterey chapter of Surface Navy Association.

21 APR 93 Completed master compilation of all design project reports into one report.
